HEW [illegible]NG DATA ON PRIVATE REHABILITATION OF DISABLED

The Office of Vocational Rehabilitation has made a grant of $5,300 for a survey of expenditures by private voluntary agencies for rehabilitation of the disabled. The grant went to the National Rehabilitation Association. The Department of Health, Education, and Welfare wants the information in order to determine what the government effort for meeting the problem should be.

OVR is spending $57,600,000 for rehabilitation this year, and state agencies are prepared to spend about $28,300,000. "If we are to plan soundly for the future, the governmental agencies should know how much of the job can and will be done by the private agencies and the voluntary organizations, in turn, should know just what the federal and state agencies are prepared to do, "Secretary Flemming said.

"In that way we should be able to arrive at a reasonable and equitable division of the costs and at the same time develop more efficiency in operations through prevention of overlapping activities. This should benefit all concerned—the handicapped, the taxpayer, and the contributing public."

NATIONAL HEALTH SURVEY REPORTS ON AGED

New figures gathered by the National Health Survey show that of [illegible]7 million middle-aged people, 14,800,000 reported no long-term chronic illness. Further, 3,600,000 out of 15 million persons 65 years or older also reported no chronic condition.

The survey, started over 15 months ago, shows there is a progressive increase in the incidence of chronic illness and disability as persons get older. The existence of one or more chronic health conditions was reported for one-sixth of children, one-third of youth, one-half of 50 million young adults, three-fourths of those in middle age, and three-fourths of those who are 65 years or older.

"Fortunately, not all chronic conditions are disabling," according to Bertha Adkins, Under Secretary of HEW, "but they do impose some limitations on the activities of more than 6 million middle-aged people and on 6,300,000 persons 65 or more years of age. Among the older group, about 2,250,000 are unable to carry on their major activities of living."

MISCELLANY

A month-long course in "Principles of Medical Operations in Nuclear Warfare" is under way at Walter Reed Army Institute of Research, Washington, D. C. In attendance are 23 Army medical officers from stations throughout the world. The objective is to teach the principles involved in medical phases of nuclear war, including a review of mathematics and theory, nuclear weapons systems, phenomenology and human effects and medical plans, training, and applications. Lieut. Col. Joseph D. Goldstein is director of the course.

Col. Floyd L. Wergeland, director of the Office for Dependents' Medical Care (Medicare) has been promoted to brigadier general. He succeeded Major Gen. Paul I. Robinson in the post last September.

ISOLATION STRESS IN MEDICAL AND MENTAL ILLNESS

Eugene Ziskind, M.D., Los Angeles

Sufficiently prolonged isolation from society or deprivation of sensory stimuli can produce mental abnormalities in the form of hallucinations, anxiety states, depression, and paranoid symptoms. Conditions likely to induce these phenomena occur clinically in patients kept in the dark after cataract operations, in persons with severe impairment of hearing, in poliomyelitic victims confined to respirators, in prisoners kept in solitary confinement, and in refugees handicapped by language difficulties. Monotony and isolation also affect certain occupational groups such as long distance truck drivers, monitors of radar screens, watchmen, and assembly-line workers. The underlying nervous mechanisms are not yet understood, but prevention and treatment are simple. This is well illustrated by the experience with cataract surgery, which in the past has been followed by psychoses in as many as 7% of cases. Since improvements of technique have permitted reduction of the period of bilateral bandaging of the eyes to one day or less, the incidence of postoperative psychosis has fallen below 1%.

THAT EXTREME isolation can produce mental abnormality has long been known to psychiatrists and social scientists. Recent experiments indicate that this reaction to isolation is universal. Does the newer knowledge aid in determining to what extent less extreme degrees of isolation are stressful in medical and mental illness? What is the mechanism of isolation stress? Can it be measured? These interrelated queries will be considered.

The early psychiatric references to isolation are to the paranoid psychoses of prisoners in solitary confinement,[1] the hard of hearing,[2] and the communication-deprived refugees.[3] Children reared in social isolation,[4] e. g., the famous case of Caspar Hauser, and those raised by animals, so-called feral men, have shown retarded mental development. Recently anecdotal accounts of isolation at the Arctic and Antarctic regions and at sea have attracted attention. Of even greater scientific interest is experimentally induced isolation.

Experimental Studies

Three experimental procedures of inducing isolation are currently best known. Each interferes with the usual sensory stimuli in a different and special way. The first report was by Heron and associates.[5] Healthy college students were paid $20 a day for as long as they would stay in a soundproof air-conditioned cubicle in a comfortable bed,

eyes covered completely by translucent ski goggles, and arms and hands restrained with cardboard sleeves. Provision was made for food and elimination. A communication device extended to the observer who was watching on the outside through a window. Most subjects terminated the experiment within three days because of anxiety, and those who persevered longer usually developed hallucinations. The latter were commonly visual, but occasionally auditory or tactile. The second method was carried out by Lilly,[6] with the subjects isolated under water up to three hours. In the third method, Solomon and his associates[7] confined subjects up to 36 hours in a specially prepared tank-type respirator (with the motor going, but the vents open). The final results of various methods show similarities. Interference with normal sensory stimulation in the isolation experiments accounts for the rapid induction and high incidence of stress and mental disability.

Each group of investigators set out to separate the subjects from other persons and to eliminate new meaningful sensory stimuli. For each objective the attainment was not absolute. Although all three methods impose changes in the intensity, variability, and finer discriminations of sensory stimuli, each has a different emphasis. That of Hebb is characterized chiefly by a reduction in the patterning of the stimuli, that of Lilly by a reduction in the absolute level of the stimuli, and that of Solomon by an imposed, unvarying, and repetitious structuring of the stimuli. Actually an important common feature is reduction in the variability of stimuli. The altered sensory input is the focus of study in current attempts to clarify the physiological mechanisms involved.

Since the experiments are characterized by special interference with sensory input in addition to isolation, the question arises "To what extent are the effects due to seclusion and to what extent to the alteration of sensory stimuli?" Sensory deprivation is always a concomitant of isolation in man, one reason being that the human voice is such a significant part of the total external stimuli. In fact, clinical material points up that interpersonal isolation alone, without special sensory interference, also produces stress and mental symptoms.

Isolation in Medical and Mental Illness

Conditions associated with special sensory interference will be discussed first. The most striking clinical example of isolation stress is seen among patients with postoperative cataract psychoses. After extraction of the cataract, the patient has the unoperated eye covered as well as the operated one because this cuts down the ocular movements which might interfere with healing. A small number of patients develop postoperative psychoses. The ophthalmological surgeons have known that the majority of such cases clear up quickly once the unoperated eye is uncovered. There is much evidence that elimination of visual stimuli in the isolated patient may produce a break with reality and that restoration of visibility usually suffices to dissipate the hallucinations and other mental symptoms.

As long ago as 1890 Frankl-Hochwart[8] wrote that the chief factor was the "Abschliessung von der Aussenwelt." He noted that the incidence of postoperative psychoses in cataract extraction was higher than that after other types of surgery— 7% in the 183 cases of the famous ophthalmologist Schnabel (1880). He also referred to the experience of Schmid-Rimpler with two nonalcoholic patients, suffering with iridochoroiditis and luetic iritis (19 and 57 years of age, respectively), who were placed in a darkened room and developed psychotic syndromes. In the latter half of the 19th century it was customary to place cataract patients preoperatively and postoperatively in a pitch black room. Schmid-Rimpler in 1863 already commented that this practice contributed to the incidence of psychotic disturbances.

Later a series of advances in operative technique resulted in a progressive reduction of the number of days of required bilateral bandages and a corresponding diminution of the cataract postoperative psychoses. In the earliest days the incision into the eyeball was left to heal without sutures, at which time both eyes were kept covered three or four days. In this period, the incidence of psychoses, as judged by the report of Parker (1913), was 3%. Then followed the general acceptance of conjunctival sutures (probably around 1930) when two or three days of bandaging of both eyes sufficed, and the psychoses were reduced to 1.5 or 2%.[9] With the introduction of deep corneoscleral sutures (generally practiced since about 1945), the bilateral bandaging could be reduced to one day or less. Correspondingly, the complicating psychoses dropped to less than 1%.[9]

So far the evidence of an etiological role for sensory deprivation in cataract postoperative psychoses is (1) greater incidence of this complication than after other types of surgery, where sensory deprivation does not occur; (2) disappearance of the psychosis in most cases when the unoperated eye is uncapped; and (3) progressive reduction in incidence of psychoses with advances in operative technique, thereby shortening the period of covering both eyes. Further approximation to the multiple sensory interference of the isolation experiments is the observation of Axenfeld (1925) that cataract patients were more susceptible to postoperative psychoses if they also had impaired hearing. Since it is among the aged that most postoperative cataract psychoses occur, it is of more than passing interest that senile patients with nocturnal delirium had the delirium reproduced in the daytime when placed in darkened rooms or when their eyes were bandaged. Cameron[10] points out that these patients have a loss of retentive ability, so that visual images must be seen repeatedly for their identity to be maintained. The data from all these sources therefore strongly support the thesis that in the etiology of the postcataract extraction psychoses isolation with sensory (visual) deprivation plays an important role.

Another instance of sensory deprivation contributing to isolation pathology is seen in the paranoid psychoses of the hard of hearing. Here the literature is less extensive than in the cataract extractions and the evidence is not as conclusive. The literature includes clinical psychiatric impressions antedating Kraepelin's contribution,[11] indirect statistical studies,[12] and experimental studies.[13] Space does not permit discussion of the interesting psychological differences of visual as compared to auditory loss, particularly since the material is not germane to this thesis.

The mental disturbances reported by Mendelsohn and Foley[14] of patients with poliomyelitis confined to tank respirators present the clinical picture of "isolation psychoses." Other toxic or inflammatory processes appear to have been ruled out. Similar symptoms occurred in normal subjects confined to tank respirators. There are then at least three clinical disorders with special sensory limitations which seemingly parallel the isolation experiments.

Highly suggestive evidence of isolation as a stress, exclusive of special sensory restriction, are the psychoses of solitary confinement[1] and of language-isolated refugees.[3] Although the paranoid state is the usual type of psychosis attributed to isolation, I have now seen five cases of psychotic depression in women whose histories indicated long periods of relatively pronounced isolation preceding the onset of the mental symptoms. These depressions were devoid of paranoid trends. In seeming contradistinction is the report of Azima and Cramer (1956) that of five patients with psychotic depression who were subjected to isolation procedure (somewhat similar to that of Hebb) for three days, two experienced disappearance of the depression and three amelioration.

It has also been my clinical impression that patients with a single phobia which underwent a rapid and marked spread to many phobias, have families who permitted them a fair degree of isolation. The experience of Freud and others that active contravention is helpful in these cases supports the impression of the salutary influence of lack of isolation.

The possible relation of some senile psychoses to isolation certainly warrants investigation. The special vulnerability of the aged with visual and/or auditory impairment has already been noted. The adequate evaluation of isolation stress in older patients is made difficult by the fact that many such individuals are already close to mental decompensation. Acute stress of various types is often followed rather suddenly by a full-blown chronic brain syndrome in subjects not at all previously suspected of deterioration. There is need for a carefully controlled study contrasting the incidence and degree of prior isolation in matched groups of aged individuals with and without psychoses. I have such a study under way.

The evidence for interpersonal-isolation or seclusion per se as a stress factor in other medical illnesses also needs to be evaluated. Two physicians who were quite isolated during their hospitalization with coronary heart attacks developed depressions. Both were formerly out-going, active individuals and they themselves felt the isolation was a contributing factor to their depressions. The effects of relative isolation on patients confined to bed with casts, with paralyses, and with debilitating diseases call for evaluation. More study is needed to determine that additional contributory factors, such as latent predisposition to mental illness, toxicity, interference with cerebral circulation, or organic neurological involvement—peripheral or central—are not the significant etiological ones. The ready disappearance of recent mental symptoms on termination of the isolation (as occurs in typical solitary confinement prison psychoses) would favor seclusion as the significant causative factor.

Practical and Preventive Suggestions

Although there is need for more investigation before the degree and extent to which isolation constitutes a noxious factor in illness can be determined, several general therapeutic and preventive suggestions are warranted. Preference for two or more patients sharing a room, instead of private facilities; early ambulation for bed patients; activity programs in hospitals; frequent visitors; avoiding or minimizing hospitalization of the aged and very young (possibly substituting "rooming in" for both old and young); and plenty of light—at times, even during the night—might all be helpful in combating isolation tendencies. Some ophthalmological surgeons have preferred to extract cataracts in aged patients in the home to avoid removal from familiar surroundings. One might want to reevaluate the use of continuous tubs or the isolation of the old rest cures for the mentally ill.

On the preventive side, social participation and activity are well known as measures for avoiding or mitigating the harmful effects of seclusion. The isolating dangers of pregnancy and the infant rearing period, of occupational retirement, of the involutional period, and of old age and infirmity call for such intervention. The realistic hazards of isolation and sensory monotony have become a matter of public health concern for long distance night drivers of trucks on lonely roads, for monitors of radar screens, and for night sentinels, as well as the belt-line worker with repetitious, near-automatic activity. It behooves us therefore to be alert to the hazards of undue isolation with or without special sensory privation in many life situations.

Mechanism of Isolation Stress

The mechanism is unknown whereby isolations, with or without special alteration of sensory stimuli, produces symptoms. Since the experiments emphasize interference with normal sensory stimulation, it is not surprising that implication of the functions of the ascending reticular system (ARS) should be suspected. There is, however, no direct proof of the involvement of this neurophysiological system. Indirect data are suggestive. Sensory input mediated through the ARS has been shown to be important for the functions of attention (and concentration), arousal, wakefulness, and consciousness.[15] A number of the known symptoms of isolation stress occur in dysfunction of the ARS.

The electroencephalographic (EEG) tracings of subjects under isolation stress [16] resemble the EEG's of persons with hallucinations produced by psychosomimetic drugs [17] or clinical states of toxic deliria.[18] (The hallucinations in the isolation experiments have been said to be like those produced by mescaline and lysergic acid diethylamide [LSD-25].) The EEG findings consist of a decrease in the percentage of alpha waves and in the appearance of slow waves. However, decreased percentage of "alpha time" or total suppression of the alpha rhythm is not synonymous with altered function in the ARS, and might presumably be due to impairment of other functions.

Direct assay of impaired functions of the ARS, as evidenced in the EEG, is being made by me in instances of isolation stress and hallucinatory states. The finding of Blum (1957) that alpha blocking is impaired in patients with chronic brain syndrome and schizophrenia and not in normal controls is pertinent. Blum's study is being repeated to ascertain whether this finding can be correlated positively with the presence of hallucinations and/or paranoid delusions. For the time being, the evidence for involvement of the ARS is only suggestive.

Another hypothesis pertaining to the interference with sensory stimuli is that of Bartlett (1951). He postulates that illusions and hallucinations may arise from distorted peripheral sensory stimuli replacing the normal ones. A patient in whom he extracted a cataract (as in another case reported in the literature) had hallucinations in a blind area which Bartlett attributed to abnormal sensory stimuli from the altered peripheral optic structures. He further refers to reports in the literature on phantom limb which support his thesis. Amputees with phantom limbs will often lose the perception of the hallucinated limb while the nerve endings in the operated stump are being tapped. It is Bartlett's contention that the transmission of normal sensory stimuli from the periphery is necessary for accurate central (perceptual) interpretation. In patients with blind and anesthetic areas there are usually no hallucinations. Only when peripheral structures create abnormal sensory stimuli, such as optic scars or amputation neuromas, is there abnormal perception. The normal sensory stimuli from tapping the neuroma replace the abnormal stimuli and the hallucinated limb disappears. Hebb and his group also support the role of varied sensory input for normal mentation. Is it possible that in the isolation experiments there is loss in the normal variability of stimuli (or some other alteration), so that realistic interpretations are no longer made—that the "corrective" influence of normal stimuli is absent under these conditions? This hypothesis warrants further analysis and testing.

Even though the exact mechanisms of isolation stress are not known, measurability of that stress would be of great clinical value. Such knowledge would perhaps enable one to differentiate those patients who break under isolation stress from those who do not; to differentiate when isolation in any illness, or a certain special illness, plays a significant etiological role. With this end in mind, my current research includes the measuring of plasma 17-hydroxycorticosterone (compound F) and catecholamines before, during, and after the height of the stress. If the stress can be measured, solution of both experimental and clinical problems of isolation should make much more rapid progress.

Conclusions

Paranoid states in persons subjected to solitary confinement, in the hard of hearing, and in language-deprived refugees are clinical reference to the harmful effects of isolation, known to psychiatrists for a long time. The history of the psychotic complications of cataract surgery reveals the great similarity, both as to origin and as to type, between these mental disturbances and those noted in recent experimental "sensory deprivation." Other medical and surgical illnesses should be reviewed for possible harmful effects of isolation, particularly among the aged.

Improvements in medical care and prophylactic measures based on avoidance of isolation stress can be recommended even now. The isolation stress may be due to interference with mediation of sensory functions via the ascending reticular system. The evidence is still inconclusive. Electroencephalographic studies are under way to investigate this point. Measurement of isolation stress would promote objectivity in the clinical and experimental studies. Perhaps the determination of the level of plasma 17-hydroxycorticosteroids and the catecholamines will serve this purpose.

DESIRABLE ATHLETICS FOR CHILDREN

George Maksim, M.D., Washington, D. C.

A program of athletics for children should be such as to contribute to their total fitness, which embraces physical, mental, emotional, moral, social, and spiritual values. Such a program should enlist children not as spectators but as participants and should therefore be adapted to the developmental level of the children. It should be diversified rather than one-sided and should not involve the physical risks of such sports as boxing and tackle football. It should be confined to the local community, and the participation of children in national competition is to be deprecated. A program that is backed by a group of informed and mature adults, is planned with the best interests of the children in mind, and gives opportunities to the slow learners and the handicapped deserves to be encouraged and helped by the physicians of the community.

"What are desirable athletics for children?" This is a question that can be quite properly raised in this era of discussion pertaining to fitness of American youth. Some of the leaders in discussions in this area would purport that their ideas of a suitable program of athletics will produce optimal fitness of youth. It would be well here to pause and consider what is meant by youth fitness and what part athletics should play in its promotion.

Fitness for Living

We are really seeking the total fitness not only of the young but of all individuals. This has always been a goal of members of the medical profession. It is particularly true among those of the profession who supervise the growth and development of infants and children. The term "fitness" has been variously defined, but essentially it should mean the total well-being of each individual during his formative years and in adult life. It does not mean simply the absence of illness or the existence of superior muscle strength or agility.

An interest in fitness, however the term may be defined, is not new to American physicians. It has been of concern to members of the American Medical Association since its organization in 1847. Public health physicians also have had an avid interest in, and concern for, health protection and, therefore,

---

Read in the Symposium on Competitive Athletics in Children before the Joint Meeting of the Section on Pediatrics and the Section on Preventive Medicine at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

the development of fitness ever since local governments assumed any responsibility for public health.

We Americans have always had an understandable pride in our physical and moral strength. Generations have gloried in the courage and hardihood of the early settlers, the endurance of the pioneers who broke the wilderness, the capacity of young men to survive in the wars, the ability of our people to adjust to the stresses of a complex civilization.

The question now is, "Are we fit to cope with the tasks of our time?" Today, America finds itself in a complex world situation that is uncertain in the demands made on the physical, mental, moral, and spiritual resources of the people. It is a period when our nation must be strong. It is a time when all of us—physicians, teachers, and all citizens—have increased obligations and opportunities with respect to fitness for living.

It would be well here to make some further comment about the definition of fitness. As I implied earlier, some think that fitness is related solely to measurement of strength and flexibility of certain muscles. The following story was presented on the radio some months ago:

> They say Africa is a continent of strange contrasts. And Mal Whitfield, America's two-time Olympic 800-meter champ certainly agrees. He learned first hand on a recent State Department goodwill tour. Whitfield was supposed to show a group of natives something about physical training. Mal did a push-up and then asked his group to do likewise. One native after another tried but no one succeeded. Exasperated, Mal tried a different exercise. Just then one of the natives leaped over a fence and disappeared. Whitfield was bug-eyed. The fence was a shade over seven feet high. Then another native raced past him and into the forest. "Where's he going?" Whitfield inquired. "To catch an antelope," was the answer. Mal shook his head and walked away muttering to himself, "And they couldn't do a push-up."

These, and many other illustrations might well pose the question, "Fitness for what?"

We should always continue to think of the total fitness of the total child, and, may I repeat, a true concept of fitness embraces physical, mental, emotional, moral, social, and spiritual values. It includes every child, the handicapped and his rehabilitation, as well as those who are "whole."

Desirable athletics for children may make their contribution to the total fitness of the child, the youth, and the adult in several ways. Before we proceed to more detailed discussion I would like to clarify two points. First, we are discussing children 12 years of age and under (those in the pre-teen-age group), and, second, nothing which is said here must be construed as indicating denial of competition to the growing child. This cannot be done, since competition is an inherent characteristic of the growing individual. He competes with himself or others in his environment. Competition is part of our American way of life.

Characteristics of Sports Programs

There are certain characteristics about athletic or sports programs for the age group to which we refer that should be kept in mind. In fact, certain features should be emphasized and reemphasized.

Sex.—In the preadolescent group, both boys and girls should be considered equally. Girls in this early age should not be mere spectators but should be participants. Members of both sexes should have an introduction to athletics even at the pre-school-age level—in the home or the nursery school environment. It is at this level that mastery of the coarser movements of the body should be attempted without any emphasis on winning or success. The effort should well be in the direction of improvement over past performance.

Developmental Level.—All athletic activities should be geared to the developmental level of each child and not to his weight or chronological age. Children in this immature, growing, developing stage have varying rates of gradual, or more rapid, change from the clumsy, coarse, gross movements to the more refined, coordinated, and accurate movements of skill. Running, catching, throwing, and other physical activities in athletics, sports, and games are at first quite awkward and inaccurate, but in the years to come the child may develop into a gracefulness and achievement that could not be anticipated.

Diversity of Opportunity.—All athletic and sports activities of the elementary school child should be so arranged that there is an opportunity to participate in many activities throughout the year, within and without the school program. These activities should range from ordinary calisthenics through the various sports programs in a well-regulated physical education department in the schools. These activities should be mandatory within the degree of ability of each individual child. The amount of physical exercise outside of the program is often unpredictable. Undue concentration on any one sport at this age level has rarely developed a "star." On the other hand, a program in which a diversity of opportunity is available has, on many occasions, demonstrated, as maturation occurred, latent ability in athletics that neither the parents nor other adults had suspected were present.

Perhaps it would be well if more children in this age group could follow the philosophy expressed by "'Where Did You Go?'—'Out.' 'What Did You Do?'—'Nothing'"—a recent popular book by Robert Paul Smith. Children in this age range should not be pressured into receiving adult acceptance by conforming to a rigid, highly organized, and highly competitive program in any of the sports. All sports programs should give all children an opportunity to participate, especially those with seemingly less natural aptitude. The natural athlete will emerge despite any programs.

Any program in any sport for the younger child should be confined to the local community. It is highly questionable whether state or national tournaments, or any large-scale exhibition programs, promote the maturation of a child into a youth with total fitness. The recent report by the School Health Committee of the American Academy of Pediatrics on the subject of competitive athletics recommends that contact sports, such as tackle football and boxing, not be considered as desirable athletic activities. The former has risks, and the latter also has risks and an undesirable philosophy.

I would like to take opportunity at this time to commend the program of Long Beach, Calif. This, as reported, seems to eliminate the undesirable adult pressures of programs in various sports, particularly baseball.

It has recently been reported that this year's Little League Baseball program has changed from a national to an international one, with many countries participating. Certainly, we are all currently aware that there is a great need for more international relationships, but is this the level at which it should be attempted, with a small, select, minority group of early matured children competing? Again, all youngsters, not just the natural athletes, should have opportunities for participation. Furthermore, this participation should be for the benefit of the child and should not be used as an attempt to bind faltering family relationships.

Program Planning and Supervision for Optimal Growth and Development

All athletic programs in the prepubescent age range should be planned in the best interest of optimal growth and development—physical and emotional. They should be fun and part of the joy of living and serve as a wholesome outlet for the normal energy and exuberance of the young, as well as a constructive and beneficial learning experience. Overemphasis on any one activity may produce in the boy or girl a situation where the borderline between healthy fatigue and harmful exhaustion is trespassed. The failure to win graciously or to lose stoically may be equally harmful in the emotional growth and development of a child. The picture of a boy crying after some athletic contest might be excused by some with the comments that "it did him some good to cry." However, the first question that comes to mind is "did he need to cry at all" over a childhood athletic contest which is only a stepping stone to other and more important contests?

This optimal physical and emotional growth and development should be the primary concern of all adults—parents, physicians, teachers, and recreation leaders in programs of desirable athletics for children 12 years of age and under. It is at this level that the first steps are taken toward a development of total fitness in youth to result in a happy, well-integrated adult.

Conclusions

Certain salient features for a program of desirable athletics for children may be enumerated. First, a desirable program is one which is enthusiastically accepted by the community, one which is worked out through the combined efforts of all concerned—the parents, teachers, recreation leaders, and the physicians in the community who can act as advisors. It should not include contact sports.

Second, the health aspects should be clearly set forth. Every child should have, in addition to his annual physical examination, a complete medical examination before participating to any degree in a formalized program of athletics. An injured or ill child should have the approval of his physician before rejoining the athletic program.

Third, there should be an informed, emotionally stable group of adults behind every program of athletics. Parent-teacher associations and other civic leaders can exert an influence in this direction which will provide for the better utilization of existing facilities, as well as provision for necessary facilities where they do not exist. Gymnasiums should not be changed to science classrooms and laboratories—we need both.

Fourth, all desirable physical education and athletic programs should be for all children and suited to their developmental levels, and they should make provision not only for the talented but for the slow learners and the handicapped.

Finally, it is not only the physician's concern but his responsibility to exert his influence and assist in the development of programs of desirable athletics which will have as their primary interest the total well-being of the total child and the prevention of potential inadequacies when that child reaches adult life.

THE OLDEST LIFE INSURANCE COMPANY.—The first life insurance company, "The Corporation for Relief of Poor and Distressed Presbyterian Ministers and of the Poor and Distressed Widows and Children of Presbyterian Ministers," was established [in 1759] in Philadelphia by the Synod of the Presbyterian Church. This company, now Presbyterian Ministers' Fund, is the oldest life insurance company in continued existence in the world.—Life Insurance Fact Book, Institute of Life Insurance, New York, 1957.

EDUCATIONAL ASPECTS OF ATHLETICS FOR CHILDREN

Fred V. Hein, Ph.D., Chicago

A program of athletics is important in the education of young children, and competition is a vital part of the experience. But competition is excessive if it results in emotional stress beyond the capacities of a child, entails undue risk of permanent physical deformity, or diverts so much of the school's equipment, attention, and time to a few physically gifted children as to deprive many others of opportunity for participation. The ideal athletic program provides opportunities for all boys and girls; it should be diversified and graded. It should be planned in a way that will not permit exploitation of children by adults for selfish or commercial reasons, and the motivations provided by occasional interscholastic events should be used to bring the benefits of active sports participation to the greatest possible number of children.

Few problems have been subject to as much misquotation, distortion, and misinterpretation as the issue of athletics for children and youth. So before getting to the basic problem it may be helpful to clear away a number of side issues that have frequently caused trouble in such discussions.

Educators, like the medical profession, are divided on some of the issues involved. But there is a body of reference such as the views expressed by the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association. Pertinent recommendations, reflecting the combined views of educators and physicians, are also available in the reports of the National Conferences on Physicians and Schools, sponsored by the American Medical Association.

Such groups have strongly favored competitive sports for children and youth at suitable age periods, of appropriate kinds and under proper supervision. In fact, they suggest more competition in more sports, with more teams, and more individual activities for more children of both sexes. However, the word controlled should be emphasized. One may wish to control competition in terms of the maturity of the competitors, but this can in no way be interpreted as being against competition. A common misrepresentation is to label anyone who proposes athletic controls as being opposed to competitive sports. On the contrary, those who advocate such regulation do so in the best interests of athletics. It is only through proper regulation that sports can provide their optimum benefits for children and youth.

Not every aspect of education can be predicated on objective evidence. Experience must have its due and there is still a place for reason, logic, and interpolation in human affairs. In developing our programs of sports for children and youth, we should certainly utilize every bit of objective evidence that is available to us. But in the absence of such evidence and for problems that do not lend themselves to objective research, we must rely on reason and common sense.

Definitions

One of our problems in discussing what is desirable in a sports program for children and youth is definition of terms. For purposes of this discussion, we are concerned primarily with children of upper elementary and lower junior high school age. As a general rule these youngsters will be under 13 years of age and in grades below the ninth. Athletics and sports are used synonymously to include individual, low organized and team games, and also tumbling, rhythms, and conditioning activities. Competition is used broadly to cover competition against one's own past record, against other individuals, and as a member of a team against another group.

The terms "high-pressure program" and varsity-type program are used to indicate an athletic program for young children which simulates that of the colleges or professional sports. These terms refer to programs for young children which include championship schedules, long-distance travel, all-star teams, tournaments, bowl games, and the like. They also refer to any type of athletic program which is developed in terms of adult satisfaction rather than the needs of children and youth.

Competition and Cooperation

This brings us to the matter of cooperation in relation to competition. We need to look carefully at these two terms. They are not, as some people would have it, in conflict with each other. Competition is a part of our way of life, a valued American heritage. To it we attribute much of our progress in science and industry, our superior standard of living. Cooperation also is an essential factor in human affairs. Many of our endeavors depend for

Read in the Symposium on Competitive Athletics in Children before the Joint Meeting of the Section on Pediatrics and the Section on Preventive Medicine at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

their success on the quality of cooperation achieved. A happy mixture of the two, competition and cooperation, makes for effective living in a democracy.

The ability to compete ethically and to cooperate effectively must be learned; no one is born with these skills. Athletics furnish one medium for such learnings—both competitive and cooperative. The player must do his part as an individual competitor but must also cooperate with other members of the team. Athletics then require a mingling of competitive and cooperative effort analogous to real life. Because they are so absorbing to youth they have their own self-contained motivation. This makes properly developed athletics particularly potent as a means of education for both competition and cooperation.

Our discussion here is confined to the former but not with the question of competition versus no competition. Competing is an inherent part of living and learning. To even suggest its elimination is ridiculous. So our problem is to decide on the desirable intensity of competition for the younger age group and to outline the kind of athletic program that will permit us to maintain this desirable intensity. In attempting to do this we must look at both health and education factors. Educators rightly turn to physicians and physiologists for guidance relating to the health aspects of athletics. But queries concerning the effects of varsity-type athletic competition on young children bring varied answers:

Rowe[1] and Fait[2] conclude from studies that young participants in interscholastic sports do not grow as well as those having a well-organized physical education program. McCraw[3] reporting the results of another study indicates that those taking part in interscholastic sports show a greater rate of growth and physical development.

Lowman[4] surveyed his orthopedic colleagues and found the great majority opposed to "varsity-type" interscholastic competition below the ninth grade. Fait[2] a few years later, with the question worded somewhat differently, reported that a majority of orthopedists responding made the opposite kind of response.

Promoters of midget football leagues point to their records of relatively few apparent injuries as proof that the sport is as safe for youngsters as for their older brethren. But studies of injuries at the high school level[5] show that the younger and greener a youth the more likely he is to injury. That all serious injuries are not apparent was demonstrated when x-ray studies of so-called insignificant injuries revealed 14 fractures.[6]

Similarly, it has been indicated that susceptibility to epiphysial injury in the young athlete is not sufficient to contraindicate high pressure competition in contact sports.[2] However, Hibberts' analysis of football injuries[5] shows that one out of five participants will sustain an injury. Of these injuries one out of five will be a fractured bone. Other reports[7] suggest that in fractures of the growth areas of long bones in youngsters about one out of eight will give trouble with possible deformity in spite of the best of medical care. It has also been pointed out that the hazards in this connection are greatest in contact sports such as football.

Another facet of the injury problem is related to what Lowman[4] labels "wear and tear" on the immature organism. He suggests that acute trauma may be less important than continuing minute trauma to the growing skeleton. Early arthritic changes, low back and sciatic symptoms, and other similar problems, he feels, can frequently be attributed to the cumulative effects of such minute trauma. The counter argument is, however, that those youngsters able to make the high-powered teams are more mature physiologically than their fellows[8] and consequently can stand up under the stresses of sports without such harm. And so the controversy continues.

"But what about the effects on emotional health?" the educator asks. There have been attempts to get at this experimentally: In one study employing a galvanometer-type instrument,[9] reactions of boys to their ordinary physical education activities were found to be as pronounced as those evidenced in connection with varsity-type contests. On the other hand, in another study comparing simulated pressure situations in sports with those in which pressure factors were not introduced[10] reactions of participants differed markedly. As high as 30% experienced nausea in the pressure situation while only one boy was so affected among all the participants under nonpressure conditions.

In a survey of parental opinion about sleep and sports a large majority of parents said that the participation of their youngsters in varsity-type games did not interfere with sleep.[9] On the other hand, Giddings[11] in sleep studies using standard levels of motility, as a measure of soundness of sleep, found that, in young players, highly competitive sports measurably interfered with the depth and nature of sleep.

Certain objective evidence probably relating to emotions and injuries is indirectly available. Athletic injury statistics show four or five times as many serious injuries in games as in practice periods[5]—this in spite of the fact that the time spent in practice ordinarily averages a great deal longer. The higher proportion of injuries in the highly organized situation can probably be traced to accompanying tensions and pressures. Therefore, the implication is that the high pressure conditions will create a far greater injury hazard. But those who do not agree say that these statistics are from studies of older age groups—high school and college. "How do you know they will apply for the younger, more plastic children?" they ask.

Also, on the emotional side psychiatrists and psychologists have been polled as to their feeling about the effect of high pressure sports on young children. There was general agreement that high pressure elements are detrimental at this age level.[12] But they point out that such elements are not part of the athletics themselves but of the conditions surrounding them. These, the mental health experts say, should be eliminated or controlled. This is easier said than done, however, and they offer no specific formula for such control.

There is no lack of agreement among physicians or among educators concerning the need for medical controls in sports for youngsters. Everyone recognizes the need for a medical examination prior to the season of participation, for a physician being in attendance at contests in strenuous or body-contact sports, for medical determination of ability to return to play following an injury, and other such controls. It is only on the question of the desirable intensity of the competition that disagreement exists.

Educational Considerations

Where does this lack of agreement on the effects, physical and emotional, of high pressure programs leave us? It implies that the decision as to the intensity of athletics for children must be predicated largely on educational considerations. Let us examine some of these factors that need to be evaluated:

Growth Factors.—Child growth and development specialists point out that the chief business of the growing child is to grow. Growth is a highly demanding energy-consuming process with which nothing must be allowed to interfere.[13] Rational activity will assist growth, but unreasonable stress, emotional or physical, can have the opposite effect. The child may be pushed into a fatigue cycle [14]—fatigue, impaired nutrition, impaired general health, decreased ability to rest, greater fatigue—again around the cycle.

Learning and Emotions.—Psychiatrists and psychologists agree that growth toward mental-emotional maturity and stability must be a gradual process. We do not teach children to swim emotionally by throwing them into an emotional stream beyond their depth.[15] On the other hand, we do not help them to learn how to handle their emotions by removing the problems and situations that generate emotions. For the growing child, the emotional hurdles must be neither too high nor too low; they must be consistent with mental-emotional maturity. It is the eventual task of educational leadership to evolve a graduated curriculum for emotional growth based on such principles.

Education in Values.—Football fever or hoop hysteria need not be serious diseases. Within reasonable limits they are probably good for school, community, and even national morale. Certainly they are a part of today's culture. But for most people these are transient things, held somewhat apart from the workaday world. When they become one's only world, trouble is ahead. In today's society it is easy for the athlete to feel that sports make the world go around, or at least make education go around. This is a snare and delusion except for a relative handful who will earn their living as professional athletes. For the rest such a false set of values is completely unrealistic. It is the task of education to develop its athletic programs so as to place sports in their proper perspective in total living.

Motivation of Sponsors.—Adult volunteers who give their services unselfishly to children deserve our highest commendation. The great majority who urge or promote high-powered sports for children are honest in their convictions. They feel strongly that such promotions are good for boys and girls. The same can be said for a great many parents. But child psychiatrists suggest that the motives of such parents and volunteers be examined and reexamined to be certain they are what they seem,[16] and that they stay that way. Do the inner motives jibe with those that show on the surface? Is there a desire to relive athletic successes in the child? Or conversely is there a wish to make up for youthful athletic frustrations? Does the role of coach or manager have an inordinate appeal in relation to the concern for children? These are only a few of the questions that need to be asked.

Social Learnings.—We claim certain social values for athletics; educators would be the last to deny these. Sports, properly guided, can help to build qualities like loyalty, courage, and over-all good sportsmanship. They can contribute to the development of leadership ability. They can teach the importance of both individual effort and team play. But all of these values and some others can be realized for children right in their own schools and communities without high-powered tournaments, bowl games, and the like. To claim any special social values for an athletic trip across the state or nation is simply not facing facts. These same values could be gained from a band tournament, outing activities, an educational excursion, or simply a trip with family or friends.

Educational Exploration.—Most of us would probably agree that interests are founded largely on experience. Children learn to know and enjoy a variety of sports only by participation in them. If they are to develop broad interests there should be opportunity for wide athletic exploration during the upper elementary and early junior high school years. By introducing high pressure, varsity-type programs at this most impressionable age, we tend to crowd out other activities, and encourage early specialization. Thus we deprive children of many other sports experiences as well as the opportunity for participation in a variety of other developmental activities. Also, by centering attention on the so-called major sports, to the exclusion of others, we sow the seeds for "spectatoritis" in later life. Few people participate in the major sports past age 25. And few people who have not learned to enjoy the minor sports in childhood will be converted to the active life in adulthood.

Learning Skills.—Experience indicates that children can learn sports skills much earlier than has commonly been thought. Interestingly enough, however, the earlier they are learned the sooner interest seems to drop off in the average individual. With the exception of the star performer, there seems to be a fairly constant interest-span for participation in a given sport. Educationally, then, the problem becomes one of determining when children are ready for best learning in a given activity and over what period the experiences provided will be of greatest value to them.

No one should or could justify a sports program for young children designed solely as a "farm-system" for high school and college teams. But there is nothing wrong with the concomitant development of good performers through a program designed for children as they are. Harry Combes, coach of the University of Illinois basketball team, writing with Clyde Knapp [17] contends that an extensive program for all is better training for over-all future athletic success than intensive competition for a few. The early maturers who receive all the attention in the intensive program may not be the best prospects in high school and college years. Meanwhile those who mature later and might end up as superior performers lose interest because of lack of opportunity.

Physical Unfitness.—In many areas of education, the gifted child has been neglected. But in physical education including athletics this is certainly not the case. The physically gifted child has usually had the cream of facilities, equipment, and time and attention from personnel. Frequently, this has meant that there has been little or no sports program for other children. At the elementary school level, as a general rule, facilities and personnel are too limited to support both programs. With our crowded schools these conditions are not likely to improve in the near future. Thus, those who are mostly physically fit are likely to receive the major share of attention. Such a program can help to perpetuate physical unfitness among the many children so deprived of opportunity for participation.

What Kind of Program?

Athletic competition needs to be as carefully graded as other parts of the school program. In the early school years (grades 1-3), young children find enough and suitable competition in informal play and their class activities in physical education. As the child grows older (grades 4-6) a desire for further competitive activity shows itself. Boys and girls begin to enter the team game stage and as time goes on will turn more and more to this type of play. An athletic program which includes only a few children of only one sex cannot satisfy this need. What type of program should we recommend? [18]

First, a broad program of class instruction in physical education for all boys and girls is needed. Opportunities to learn skills in a wide variety of games and other activities should be emphasized. This requires definite teaching and not merely the throwing out of balls for unsupervised play.

Second, a varied program of informal play opportunities and intramural sports should be offered for boys and girls in the upper elementary and early junior high school years. In such activities competition is confined to games and contests between teams within an individual school.

Third, occasional invitational games, sports days, and play days involving two or more schools may be arranged. Such activities are limited to neighboring schools or to a small geographical area. The emphasis is on informality without high pressure elements such as championships, tournaments, all-star contests, and the like.

A three-point program like the above makes the best possible distribution of available funds and facilities among all children. It provides satisfying activities for girls as well as boys, for the child with average skills, for the physically gifted, and even for youngsters with handicaps. Such a program spreads the benefits which competitive sports hold for children to all those who wish to take part. It permits the curriculum in competition to grow and develop a pace consistent with the maturity of the child.

Problem Practices

Immature boys and girls are not little men and women; they need a program specifically tailored to their needs. Yet bowl games, all star events, and other activities that tend to force patterns of sports designed for college and professional athletes down into the elementary schools are being pushed in some places. This has led a variety of professional groups interested in the health and welfare of young children to recommend against the following types of procedures and programs: (1) tournaments, frequent contests, long seasons, bowl games, or other procedures that may cause undue pressure or make excessive demands on young boys and girls; (2) games and contests played at night or other times outside usual school or recreational hours; (3) travel beyond the immediate neighborhood or in the case of smaller rural schools to nearby communities; (4) "grooming" of players for high school teams or attempts to make elementary school sports a "farm system" rather than a program for the children themselves; (5) commercial promotions which under various guises seek to exploit youth for selfish purposes; (6) programs which usurp a disproportionate amount of facilities, funds, and staff time for a selected few rather than for all children; and (7) overemphasis through tournaments, bowl games, "all-star" teams, and other emulations of adult athletics.

Summary

Under good leadership athletics can help to teach moral and spiritual values—to mold character. They can provide wholesome recreation, for both the present and the future. They can help to build organic vigor and improve strength, agility, and endurance. But these values are not an automatic outcome of athletics. They will not accrue unless the sports program is developed with consideration for the physical, mental-emotional, social, and educational principles involved. They cannot be achieved if the sports program includes only a few children and a limited number of activities.

This calls for a reemphasis rather than a deemphasis of athletics. It demands an athletic program that is available to each child attending school so that no boy or girl is denied an opportunity to gain the values of sports participation. Second, it requires medical supervision to make certain that the program will be conducive to the health and safety of each child who participates. Third, it necessitates planned interpretation of that program to the community—to build public understanding of the real purposes and values of athletics in education.

SPACE FLIGHT.—Scientists and engineers backed by the U. S. Government are headed for outer space. The cost of this campaign will be as astronomical as its objective, but the men who lead it consider its success a national necessity. They point out that the earth's atmosphere is an insignificant film, thinner in proportion than the skin of an apple, and that military technology is about to outgrow it, as it outgrew the earth's surface two world wars ago. Navigation of the air film is no longer enough. No nation will be safe unless it can also navigate the vacuum that hangs overhead. The new status of space flight, formerly made suspect by visionaries and fiction writers, was not defined in public until we recently held our Astronautics Symposium at San Diego. Planned as a small "confab" of space-minded missile men, this conference ballooned into a crammed mass meeting of engineers and scientists representing airplane, electronic, and instrument companies, as well as universities and all three armed services. A few years ago most of these hardheaded men would not have attended a space-flight meeting except incognito. Now we are eager.—Capt. W. M. Snowden, M. C., U. S. COMPETITIVE ATHLETICS FOR CHILDREN

Jean Hoxie, Hamtramck, Mich.

We all agree that the three things a growing child needs most are food, sleep, and exercise. Parents stress the first two and overlook the last. Allowing the matter of exercise to take its own course is not too bad, since the child's interest to use his body is so strong. But a young one does need guidance in the amount and kind of exercise he takes and a constant check on his inclination to overtax himself.

The "Golden Rule"

We will assume that every competent, successful coach is familiar with and able to impart the basic fundamentals of his or her effort, so let us pass on to some of the things common to all sports. One of the things I, myself, consider more important than whether Johnnie can break 70 in golf, win tennis matches 6-0, or even be a star in touch football or track, is sportsmanship. Sportsmanship is, after all, only an application of the "golden rule."

One of our authorities on child development said, "All young children are poor sports; an average child takes about 15 years to develop to the point where he can conform to adult standards of good sportsmanship. When children are poor sports they do not have warped personalities; they are not potential criminals; they are just downright spoiled; they are children behaving like children."

A child who is a poor sport can hardly grow up to be a good citizen. Let's face it: good sportsmanship begins at home. If mother pouts at the bridge table or father burns after a missed putt, children think it is accepted behavior.

Children, whether players or spectators, also take their cues from their coaches. An undignified, ill-tempered coach who curses, boos, jumps up and down, protestingly storms out onto the floor, or throws up his hands after losing a game or point is hardly setting an admirable example. A wiser coach or parent recognizes achievement and applauds good play of both teams.

Give your children time to develop. When they make a mistake, talk it over with them. Encourage them to play with their contemporaries. Children learn sportsmanship from playing with other children. You will be surprised just how much they learn and how fast. It is better when they are all about the same age and size; then, no one child can dominate the others. Everyone faces the fact of winning and losing.

Competition in athletics for children can serve as a positive force if every child learns to take losses as well as victories. Competition among children should not follow the intercollegiate pattern of worshiping the star performer and neglecting the unskilled. It should, instead, be kept within such bounds as to promote both the growth of the child's body and the development of a personality.

Success and Failure

Another thing we must consider is failure. Don't be too quick to decide that some child has failed to learn some particular physical skill. Give him plenty of time and some extra coaching on the side. Never ridicule his awkward early efforts. Usually failure to master some desirable skill, such as being able to catch a ball, hit a drive, or make a short putt, is caused by a lack of opportunity to practice or by self-consciousness.

Too much striving? Don't let the child push himself past his own capabilities. Keep him competing with those of his own age level. Do not let the child become overtired. This fatigue could be caused by inadequate food, lack of sleep, overexercise, emotional frustration, or all four together.

We cannot have a successful sports program without competition—but perhaps not the kind of competition we have on the intercollegiate pattern of men's sports, with its ballyhoo, its insane and inane worship of star performers, its attention to the skilled and neglect of the unskilled, and its sporting followers who demand victory at all costs.

The prime objective for any person, child or adult, is mastery of the game within the limits of his capabilities. In addition, the tremendous sense of achievement that comes from doing something well may be an aid to successful personality development in the child. The habits of diligence and perseverance necessary to achieve mastery and also to retain mastery of a sport should serve the child both in the athletic situation and also in other situations which the child might meet.

Competition, if not viewed as the prime goal but rather as an additional goal, may serve in a positive manner. It is not desirable to let the child stay in an "ivory tower," where his supremacy is never threatened. On the other hand, great care must be exercised that the child is not put in a situation where defeat is inevitable and to which he can react only with despair and withdrawal. Where a child has a reasonable chance for victory and when

he is aware that mastery of the game is his prime goal, competitive athletics then serve as a positive force, for every child must learn to take losses as well as victories.

In the last analysis, it is the coach who senses his pupil's needs and limits, who is able to make competitive athletics a positive force for growth and personality development in his students.

IMPLICATIONS OF LONGITUDINAL RESEARCH IN FITNESS PROGRAMS

Robert W. McCammon, M.D.
and
Alan W. Sexton, Ph.D., Denver

Fitness at best is a vague concept which can only be defined in terms of the purpose for which the individual desires to be fit. Fitness at a given moment may fail to reflect or predict fitness as briefly as six months from the testing. Fitness at the time of testing may vary remarkably, dependent on the standard of measurement used. The response to conditioning programs, such as athletic participation, is a highly individual thing rather than a group or age phenomenon. Children and young adults who show no frank disease are generally and similarly fit. The expectation is unrealistic that any conditioning program applied to a general population of any age level will produce uniform response.

The desire of each generation of parents to have its children grow up to be the sort of superb physical specimens that the parents would themselves like to have been is as old as civilization. The means most frequently chosen to attain this end has been some form of athletic participation. The selection of this means seems to rest equally on our concept that the athlete personifies physical vigor and on the practical consideration that it is easier to gain the cooperation of children in games and sports than in other forms of activity.

War has always been the most potent stimulus toward seeking greater fitness in the population, though the industrial revolution, with its example of physical degradation incident to urbanization and coupled with long working hours under miserable conditions, also served to intensify the cries for a "sound mind in a sound body," across the European world. Between periods of crisis such as these, the distaste with which the usual parent approaching middle age views his diminishing physical equipment suffices to make him vow that his children will never come to this but will develop all the physical attributes the parent either never had or will never have again.

In our day, with the span of useful adult years increasing rapidly, the descriptions of the decaying state of our youths' fitness are not in any real sense different from the descriptions voiced during the reign of England's first Queen Elizabeth. Again, it is children at whom the programs are primarily aimed, with at least 10 admonitions to slow down activities and avoid physical stress after the age of 30 for each lonely voice raised to advocate two-mile runs before breakfast daily for those of 50, bicycling to the office at the age of 60, or parachuting into rivers for octogenarians. Still, there have always been critics of those who stress conditioning of children. Aristotle said in his "Politics," "Of those states which in our own day seem to take the greatest care of children, some aim at producing in them an athletic habit, but they only injure their forms and stunt their growth. . . . The evil of excessive training in early years is strikingly proved by the example of Olympic victors; for not more than two or three of them have gained a prize both as boys and as men; their early training and severe exercises exhausted their constitutions. When boyhood is over, three years should be spent in other studies; the period of life which follows may then be devoted to hard exercise and strict diet."

It is not our purpose to join forces on either side of this argument. We simply wish to present data on various forms of fitness testing which we feel are adequate to support the statements that fitness at best is a vague concept which can only be defined in terms of the purpose for which the individual desires to be fit, that fitness at a given moment may fail to reflect or predict fitness as briefly as six

months from the testing, and that fitness at the time of testing may vary remarkably dependent on the standard of measurement employed.

Methods of Study at Child Research Council

The Child Research Council has been engaged for the past 28 years in a form of investigation involving repeated examinations of the same group of individuals at intervals during their entire life spans. The childhood period is interesting and important, but it seems reasonable to suppose that much of its interest and importance is derived from its impact on the events to come in the much longer span of maturity and senility. We feel that one of the major deficiencies in our knowledge of human biology is the lack of serial investigations on man which would not only permit us to know what happens throughout childhood but also give us an opportunity to trace the influences of these childhood events insofar as possible in the mature person. With regard to the present discussion, for example, we hope to be able to say in the years to come whether, as an adult, the child who was athletic and apparently fit before and during adolescence is more or less fit and longer or shorter lived than his contemporary whose measurable fitness was less outstanding in his growing years and whose participation in athletics consisted of ownership of season tickets to all the athletic events. To this end we have been administering bicycle ergometer tests to our subjects for the past 18 years, and we have added other forms of testing within the limits of our situation as the tests became available and attained acceptance. The ones in charge of this discussion very kindly granted us permission to present data for the entire span of years we have covered in this program rather than limiting us to the age of 12 years.

The study series of the Child Research Council is composed of children born in middle and upper middle class Caucasian families in Denver. Because of this selection, any limitation of nutritional, educational, athletic, or other opportunities is largely the result of individual choice rather than environmental pressures.

The presentation of data representing the performance of single individuals, where only a very few can be crowded in to the space available, is always subject to the danger of selection on the basis of proving a point with a series of three or four cases. We were somewhat protected in this instance because of the orientation of this discussion. In accordance with that orientation, we divided our children into three groups: (*a*) those who have participated in team sports where they have been subjected to organized programs designed to increase their physical fitness with an eye to competing with other teams; (*b*) those who have been more individual in their activities and whose conditioning depends practically entirely on their own initiative and energy; and (*c*) those who have never wilfully participated in athletics and have taken part in compulsory physical education in school only under protest. From these we then selected the three individuals in each category for whom we had the longest and most nearly complete follow-up records. The grouping of individuals in the figures was done with deliberate bias, which will be explained separately for each figure.

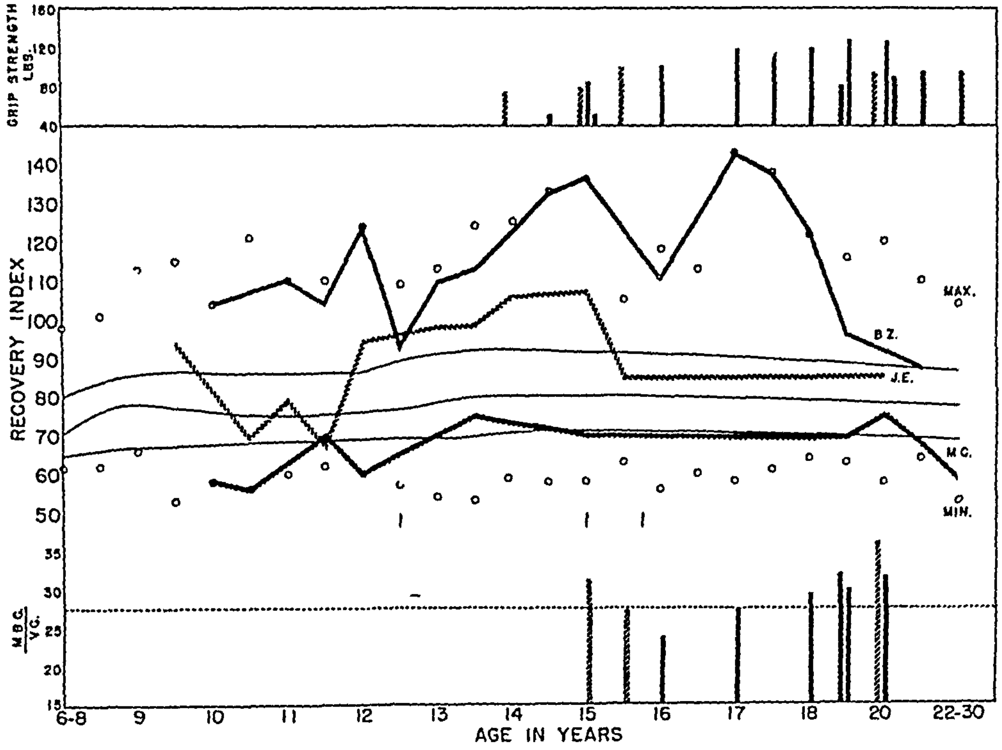

Fig. 1.—Physical fitness values for team athletes (solid line), individual athlete (striped line), and nonathlete (line of circles).

The material presented in the figures represents the results of four tests performed periodically on the subjects of the Child Research Council. The central line graph gives the range of scores by sex for the pulse recovery index, as calculated by the formula of the Harvard Fatigue Laboratory, after four minutes of exercise on the bicycle ergometer with the friction load adjusted in such fashion that the subject does ±5% of the same amount of work that he would have done on a standard step test. The circles above and below the central lines represent the maximum and minimum scores recorded for each age. The things which have interested us about these data are the relatively narrow range of distribution for the middle 50% of the group, the marked skewing of the data upward as compared with the minimal spread below the 25%, and the flat nature of the curve. Apparently, whatever the faults of this measurement, it does successfully eliminate differences due to increases in musculature and maturity.

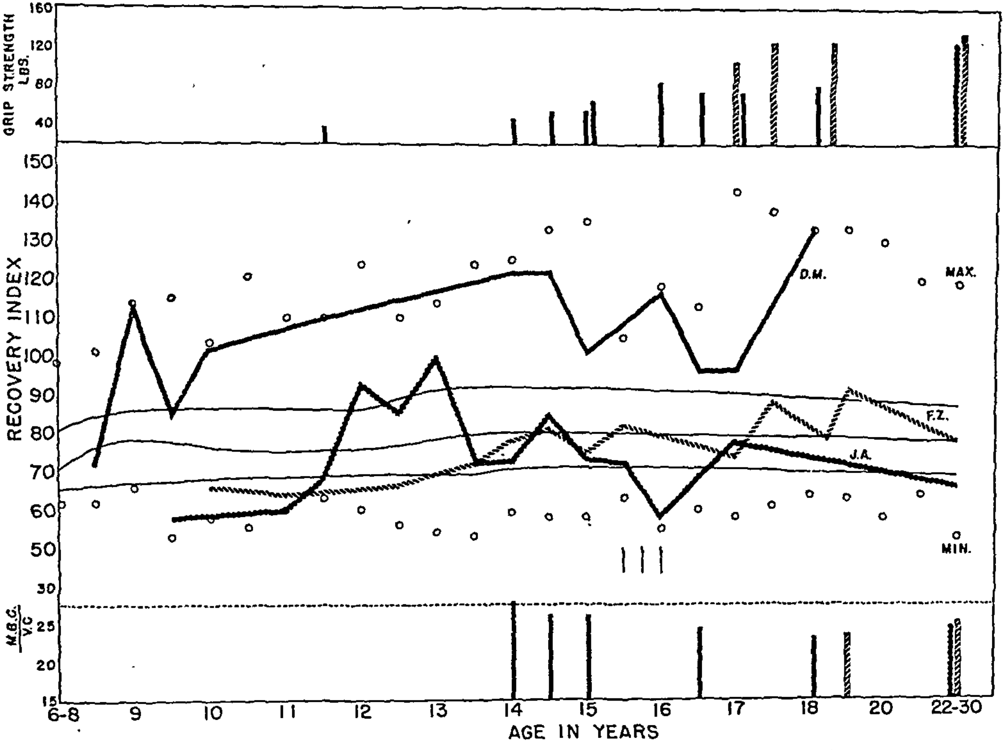

Fig. 2.—Physical fitness values, showing consistency of scores in three categories of activity for team athlete, individual athlete, and nonathlete.

The upper bar graphs give the grip strengths of the children represented. We have insufficient data at this time to establish meaningful standards for our group, but at least this permits us to compare one measure of muscle strength within these children.

The lower bar graphs represent a rather complex respiratory ratio, derived by dividing the maximum breathing capacity per square meter per minute by the vital capacity per square meter. It should be pointed out that this permits a child to show a high score either by having a relatively high maximum breathing capacity or by having a relatively low vital capacity. We have used this ratio in an attempt to express respiratory efficiency within the individual. It has the characteristic of dropping rather remarkably in a child who adds fat to the point of frank obesity. At this time we make no claims for it except to say that it seems to fit no better and no worse with our general appraisal of the subjects than the other tests used. The dotted line simply indicates the middle of the range we encounter in our subjects to give some idea of the situation of these children compared with the total group in the absence of enough data to make standards meaningful.

The small arrows indicate the age of maximum growth in height during adolescence for each of the children presented, both to give an idea of the developmental status of the subjects at any given point on the age scale and to illustrate how smoothly Aristotle avoided a difficult problem when he disposed of the whole subject of variation in the age of physical maturation by saying simply "when boyhood is over." Extreme as the differences represented here are, with the earliest peak of adolescent growth at 12 years and six months and the latest peak at 15 years and nine months, they do not represent the extremes found even in our relatively small group of less than 100 boys. The median age for maximum adolescent growth in boys for our series is 14 years, which suggests that considering childhood as terminated after the age of 12 is not only arbitrary but also erroneous.

Comparative Results

The three children grouped in figure 1 were placed together to show that, with proper selection, it is possible to fit all or most of the common concepts regarding the superior scores of the conditioned athlete no matter what type of measurement is used. The boy represented by the solid black lines was active in many sports, both as a member of his school teams and in the various "little leagues." He represents the maximum recovery index at more ages than any other child on the series. It is also true that he shows another facet of expected response, in that he stopped being active in any athletics except skiing when he finished his freshman year in college and since then has shown an abrupt drop in his score. The boy represented by the diagonally striped lines is the individual athlete, being active in swimming, skiing, tennis, and mountaineering. Although somewhat limited by going to college, he has still managed to remain active and his scores have remained fairly constant. The boy represented by the line of circles is one of the "contentedly unfit," who has successfully avoided participation in athletics and other physical activity. The fact that he had moderate asthma throughout childhood, which cleared when he was about 15 years old, may have accounted for some of his distaste for physical activity, but since he has been free from symptoms his scores have not improved.

The grip strengths of these three boys tell the same story. The conditioned athlete is clearly stronger than either of the others, and he maintains this superiority and continues to show some increase even after his recovery score has dropped. The individual athlete, while not able to match the organized athlete except briefly when he had completed his adolescence and the team athlete was just entering his, still has no trouble in staying ahead of the nonathlete in muscle strength.

In the respiratory ratio graph, however, the conditioned athlete falls behind both of the others and the individual athlete is superior. It is interesting that the nonathlete, in spite of his asthma, manages to attain a very good score, but it should be recalled that this is a ratio between two respiratory measurements and his score is aided by his relatively low vital capacity.

Finally, the early-maturing boy in this group is not the one who is athletically inclined in the usual sense, and the two extremes in athletic participation and fitness measurements are really much closer to each other in age of maturation than either is to the early-maturing boy.

In figure 2 the symbols represent the same categories as in figure 1. Again, the team athlete outstrips the other two, but this man failed to show any drop in his scores after the age of 16 when he practically stopped his participation in athletics in favor of working on his hot rod. In muscle strength, however, he is clearly below the other two boys and is actually below the median for boys of our study series. There is much less differentiation between the recovery scores of the individual athlete and the nonathlete than we saw in the first group of three. At one point, the nonathlete became athletic. Because of his late adolescence he was still preadolescent when he entered high school, and he was so anxious to demonstrate his masculinity that he went out for and made the beginning football team, in competition with boys much more advanced in maturation than he was. The score at 15 years and six months was obtained shortly after the close of the football season that year, and the dip at 16 coincided with his dropping out of football because he no longer felt the urge to prove he was a man after he had physical evidence of it.

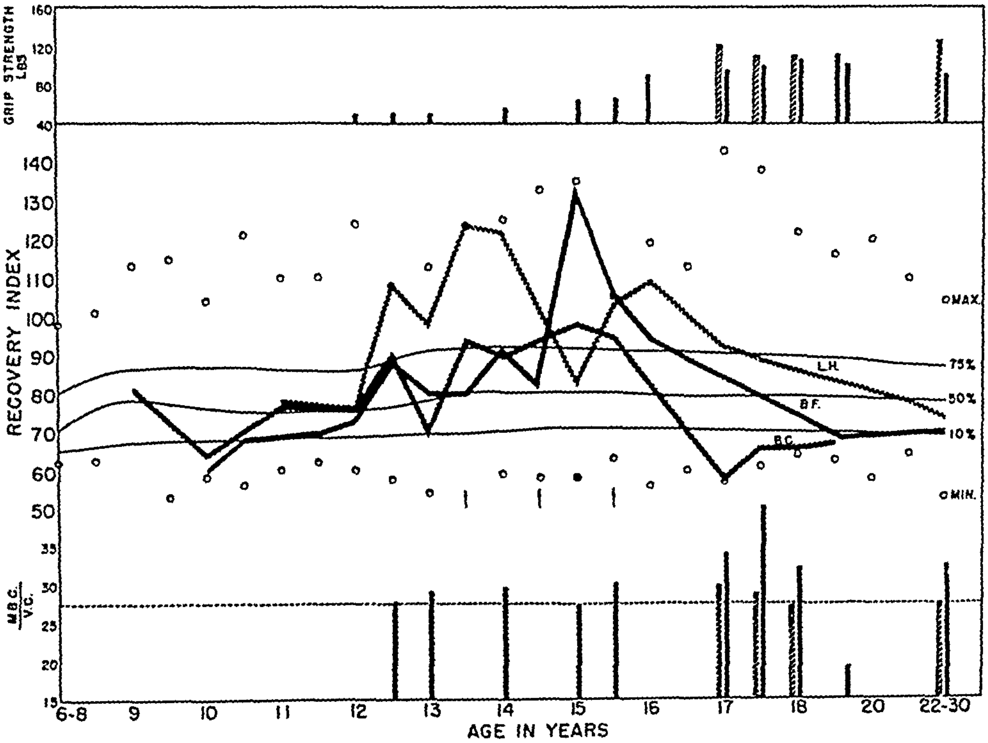

Fig. 3.—Physical fitness values, showing similarity of scores in team athlete, individual athlete, and nonathlete, engaging in three categories of activity.

The individual athlete in this group, while one of the largest boys in our group, took only a desultory interest in the organized athletic programs available to him, never went out for any school team, and preferred to spend his time and energy fishing and hiking, activities which he maintained through two years of military service and now continues as a civilian. After a slow start, his recovery index has shown a steady rise and is now in the upper half of the group. His muscle strength, as might be expected from his large size, is well up in the group, though not superior to that of the nonathlete in any significant degree. As adults, the respiratory ratios of the three subjects are quite similar, which is interesting in view of their markedly different physical builds and diverse past experiences in physical conditioning. They are also very similar in the age at which they attained the maximum rate of adolescent growth, being grouped in a six months' period starting 18 months later than the median for the boys of our series.

In figure 3, also, the solid line represents the team athlete, the diagonal stripe the individual athlete, and the small joined circles the nonathlete. If we consider the over-all picture, these three boys are not very different from each other in their scores on the bicycle. If there is a long-term edge held by any of them, it would have to go to the individual athlete, who was a runner because he liked to run in much the same fashion as Europeans run for exercise. In high school and in college he ran the mile in track, but in our area there is no competitive track activity before high school and he ran as much and as well before high school as he did afterward.

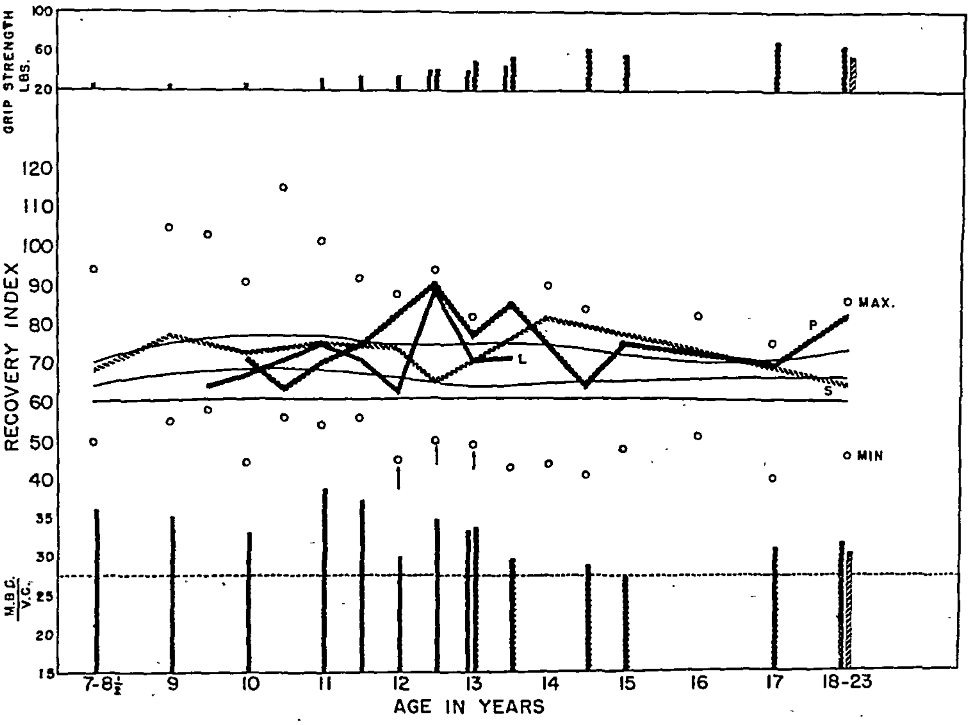

Fig. 4.—Physical fitness values in three sisters, showing similarity of scores.

The nonathlete is the brother of the nonathlete on the first chart, and, while he had no asthma, he showed the same disinclination to involve himself in athletics as his brother did. In spite of this, his scores in the early years compare well with those of the other two in all parts of the testing. At 15 years of age, he was sent to a private school where athletic participation was compulsory as a daily portion of the school curriculum, and then he went to a military school, which he still attends, where physical conditioning is part of a way of life. If these experiences have changed his physical condition, the reflections of the change in the physically stressful bicycle test are clearly for the worse, and it is only in the respiratory index that he has shown any visible improvement.

The team athlete in this group is perhaps the most interesting child and young man to be presented. From his early school days to the end of high school, athletics and physical conditioning were almost a religion to him. In spite of his ordinary muscular strength, his median age of adolescence, and his small physical size of 130 lb. (59 kg.) on a 5-ft., 8-in. (172.7-cm.) frame, he is the most accomplished athlete of our group, at least in the sense of recognition of his accomplishment. He was all-conference selection in football, basketball, and baseball each of his last two years in a tough city league, and in basketball he was repeatedly chosen by the local sports writers as the high school athlete of the week. Yet, except for the peak just after his maximum growth period and just before he entered high school, his scores on the bicycle have been ordinary enough and the decline which started during the years of intensive training was not increased in slope when he stopped athletics as a busy college student earning much of his way as a shoe salesman. Now, as a truly physically decadent medical student of 23 years, his score precisely matches his scores of 10 and 11 years when his life was filled with athletics instead of prescriptions and diagnoses.

Figure 4 was assembled to show that we do not neglect the girls. It is difficult to match the categories we set up for the boys, so we selected three sisters, one of whom may be termed athletic during the past two years since she took a serious interest in ballet. The other two have never been athletically inclined. Except for the graphic symbols, which still present the "athlete" as the solid line, it would be impossible from any of the tests to separate these girls. The established lesser muscle strength of girls is well illustrated by the grip strength results. The respiratory scores of the girls, however, are well above those shown by any of the boys. We have laughingly passed this off as expected, since everyone knows women are windier than men. But if we take a look at census or actuarial figures on the sex of those who live the longest the laugh becomes less fun.

In keeping with the general trend of those who concern themselves with fitness to make sweeping statements on limited data, we would like to point out that these three sisters raise the possibility that what we measure and term fitness is as much on a familial basis as on an environmental basis. At least so far as the bicycle ergometer scores are concerned, other siblings show the same close grouping in general as these girls show, whether they are of one sex or both. With the exception of the nonathletic brothers previously shown and one other family, the results obtained on siblings could be transferred from one child to another within a family without dislocation of the trend of any child. We do not present this as establishing a hereditary element in fitness, nor could such an element be established on a group such as ours. We do want to emphasize that the basic material which is being worked on must be taken into account along with the manner in which it is processed in the production of superior physical fitness as in the production of any other commodity.

Summary

The data collected by the Child Research Council support the point of view that children and young adults who show no frank disease are generally and similarly fit. The response to conditioning programs, such as athletic participation, is a highly individual thing rather than a group or age phenomenon, so that the expectation is unrealistic that any conditioning program applied to a general population of any age level will produce uniform response. Various measurements of fitness and response to conditioning, when applied to the same individual, give different answers, suggesting that current testing methods omit consideration of the question, "fitness for what?" There is as yet no evidence that athletics or other forms of physical activity produce any measurable or lasting benefits when applied only to children, and such adult work as is available indicates that, to be of value, the activities must continue through the major portion of the life span of the individual.

SUBDURAL HEMATOMA IN THE ELDERLY PERSON

Peter Stuteville, M.D.
and
Keasley Welch, M.D., Denver

The course of subdural hematoma was studied by reviewing the hospital records of 75 patients, 65 years of age or older, in whom the condition was demonstrated either at operation or at autopsy. The symptoms were such that the condition might easily have been mistaken for senile degeneration of the brain, cerebral vascular disease, or other conditions. Of the 30 patients who underwent operation, 17 survived and improved, while the typical course observed in 45 patients who did not undergo operation was a quiet, gradual decline, frequently terminated by sudden and unexpected death. The importance of early diagnosis and prompt operation was demonstrated. Although subdural hematoma in the elderly patient is a subtle disease, frequently disguised, it may be possible to increase the accuracy of diagnosis by keeping this condition in mind, diligently utilizing such diagnostic means as angiography, and resorting more readily to surgical exploration.

Subdural hematoma may occur at any age, and its manifestations depend on the age of its victim. The particular characteristics of the disorder at the earliest extreme of life have received wide attention, while its features at the other extreme have not. It has, however, been realized that in elderly patients subdural hematoma may mimic vascular disease or senile degeneration of the brain and that this diagnosis may be extremely difficult.[1] Moreover, the results of treatment have been poor. For these reasons, a study of the problem was undertaken in the hope that the clinical features of the disorder might be clarified and earlier recognition and treatment might thus be permitted.

Analyses [2] of large series of patients of various ages with subdural hematoma has drawn attention to the fact that the only consistent historical incident is one of trauma to the head. These studies and others [3] emphasize the variability of clinical manifestations that may appear and the unreliability of particular physical signs as a basis for diagnosis, in any age group. It is worth noting that in these extensive series patients over the age of 65 years make up only a small portion of the total numbers.

From the Division of Neurosurgery, University of Colorado Medical Center.

Read before the Section on Nervous and Mental Diseases at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

This study is based on a review of hospital records of 75 patients 65 years of age or older who had proved subdural accumulations sufficient to cause mental disability, physical disability, or death. The patients whose records were examined comprised all in this age group in whom the lesion was confirmed either by surgical exploration or by autopsy during the past 15 years at Colorado General Hospital, Denver General Hospital, and the Denver Veterans Administration Hospital.

Analysis of Cases

Age, Sex, and Race Distribution.—By far the largest number of patients (78%) were white males; only 18% of the patients were white females; and 4% were Negroes. The 75 cases studied were made up of patients between the ages of 65 and 92 years. Of these, there were 28 (37%) aged 65 to 69, 15 (20%) aged 70 to 74, 16 (21%) aged 75 to 79, 11 (15%) aged 80 to 84, 3 (4%) aged 85 to 89, and 2 (3%) aged 90 to 92.

Chief Complaints.—Escorting relatives or friends were, not infrequently, the sources from which examiners drew the reasons for a patient's delivery to the hospital emergency room or admitting ward. Often, the reasons stated seemed to represent inferences rather than quotations of complaints previously made by the patient himself.

Of these 75 patients, 32% (24) were brought into the hospital because they had suffered some kind of injury; 16% (12) because they had shown signs of mental or personality changes; 13% (10) because they were unconscious and could not be awakened; 11% (8) because of constant and severe headaches; and 4% (3) because of a neurological disability such as a hemiplegia. Twenty-four per cent (18) sought admission for medical or surgical diseases of other systems.

Trauma.—In the present series, 4% of patients entered the hospital comatose and without accompanying history of any kind. For the most part, these patients were old men who lived alone in rooming houses, where they had been found unconscious by acquaintances. A history of trauma was elicited in 71% of the cases; 31% of the patients had suffered overt trauma, as from road accidents or assault. The remainder simply had a history of falling. Four patients, resident in the hospital for nonneurological conditions, were injured on the wards, either by falling out of bed or by striking an open door during the night. In slightly less than one-fourth of all the cases, no history of trauma could be unearthed. A similar proportion of all the patients fairly certainly had been drinking at the time when the illness began.

Physical Findings.—Physical signs of increased intracranial pressure rarely were encountered. Of the patients studied, only 12 could be said to have been awake, alert, and mentally intact at the time when they were first examined; of these, 4 were injured later on the wards. The remaining patients were confused, demented, stuporous, or comatose.

Bruising about the head was remarkably frequent, being noted in over one-half of the patients. Focal neurological signs were of course, common, but since many of the patients were not examined with neurological disturbances in mind, only a rough estimate can be made about their actual frequency. Common physical findings in the patients were an alterated state of consciousness in 63 (84%) (confusion in 15 [20%], stupor in 22 [29%], and coma in 26 [35%]), bruises on the head in 44 (59%), mild arterial hypertension in 17 (23%), pupillary abnormalities in 29 (39%), speech difficulties in 11 (15%), bilateral extensor toe signs in 13 (17%), hemiparesis in 18 (24%), and evidence of alcoholism in 19 (25%).

Admitting Procedures.—As might be expected, the majority of patients with obvious head injuries were admitted to the neurosurgical service; 27% of all patients went initially to that service. Another 11%, chiefly those with clear-cut, but apparently nontraumatic, neurological disease went to the neurological service. Two patients went to the psychiatric service because of their dementia. Thirteen per cent went to a surgical or to a surgical subspecialty service with complaints or signs of such things as urinary retention, fracture, bowel obstruction, and the like. Almost half of the entire series was first admitted by the medical service. Of this number, 25% were accepted because of a history or signs of nonneurological disease such as disorders of the lungs and heart. The rest were deemed to be suffering from vascular accidents of the brain. The diagnosis on admission was subdural hematoma in 8 (11%), head injury in 19 (25%), neurological disease in 26 (35%), medical disease in 9 (12%), psychiatric disease in 3 (4%), and surgical disease in 10 (13%).

Hospital Course.—Failure to improve followed, at times, by a quiet and gradual decline and, at other times, by sudden and unexpected death seems to have been the pattern in those patients who did not come to operation. Thirty of 75 patients were said to have died suddenly or unexpectedly.

Cerebrospinal Fluid.—The cerebrospinal fluid pressure was completely normal in almost three-fourths of the 42 tests performed. Fluids altogether normal in appearance and cellular content were obtained in 40% of specimens while the remainder were xanthochromic or bloody. The protein content was analyzed in only 20 of the 42 specimens, and in 9 patients the protein level was within normal limits. Sudden death followed in one instance of cisternal puncture and in two instances of lumbar puncture.

X-rays of the Skull.—Over half the patients studied had no x-ray of the skull made at any time during their hospital stay. Of the x-rays of the skull that were obtained, one-third showed a fracture line and one-fifth definite displacement of a calcified pineal.

Operative Results.—Explorations were carried out in 30 cases. Although some 42 patients were suspected, on clinical grounds, of harboring a clot, 12 failed to reach surgery, because, in almost every instance, the patient had deteriorated beyond the point where neurosurgical intervention could be begun or completed before his death.

Of the 30 patients operated on, 57% survived the operation to improve, while the remainder died postoperatively. In half the postoperative deaths, failure to respond resulted from a reaccumulation of the clot; in the other half, such pathology as massive cerebral edema and intracerebral hematomas was found at autopsy. Contrasted to the over-all figures are the figures in the 20 most recent cases, in which 19 patients were given a diagnosis and operated on and 11 survived.

Report of Cases

Taken alone, statistical analysis of the data drawn from this inquiry is not enough to afford satisfying insight into the clinical features of subdural hematoma in the elderly patient. Simultaneous study of individual case histories is essential if the essence of the malady is to be understood.

The first case report exemplifies the commonly encountered situation in which an old man is brought to the admitting ward by relatives or friends who have noticed recently that something has been wrong with him. The patient, approached by a physician and questioned about his troubles, is likely to be grossly confused and totally unaware of the reason for his family's concern. Consequently, he tends to draw attention to such irregularities of function as his cough or his difficulty in passing urine. Duly noted, this complaint is pursued while the confusion or dementia is attributed to senility.

Case 1.—The patient was a 66-year-old man who was brought to the emergency room by his family. When questioned, he complained of frequency and urgency of some two to three years' duration. He was examined and was found to have a large prostate gland, to be confused, and to have a minimal right-sided hemiparesis with appropriate reflex changes. He was admitted to the urologic service, where cystoscopy was done and a lumbar puncture was made. On his eighth hospital day, he died suddenly and unexpectedly. Postmortem examination revealed a large, left, subdural hematoma and a massive pulmonary embolus.

Not infrequently, cerebral vascular disease seems to be a reasonably acceptable basis to account for the patient's presenting difficulties.

Case 2.—The patient was a 92-year-old man who was brought to the hospital unconscious. Ten years earlier, he had had a "stroke" that had left him mildly hemiparetic on the right side. Three days before admission, he was said to have had another "stroke." There was no history of trauma to the head. After the second attack, he went through intermittent periods of unconsciousness which gradually grew longer and more frequent until he could not be aroused. He had been noted to be somewhat weaker than usual on his right side. Examination at the hospital showed him to be profoundly comatose, to have a right-sided hemiplegia with absent tendon reflexes on that side, and to have a right extensor plantar response. He was brought into the hospital and treated supportively. He failed to improve over the next four days and finally died of extensive, bilateral, subdural hematomas.

The following case points up the fact that the early complaints of many patients of this age with subdural hematoma may be nonspecific.

Case 3.—The patient was a 76-year-old man who had been in good health until 10 days before the time when he appeared at the hospital. At the onset of his illness, he was said to have had the "flu," and he was treated for this by his family physician. During the course of treatment, however, the patient appeared to be "dull," and he complained often and bitterly of severe and constant headache. Finally, he became somnolent, and, at this point, he was referred to the hospital. Examination showed him to be in and out of stupor and to exhibit a left-sided hemiparesis with generally symmetrical but hyperactive deep-tendon reflexes and with bilateral extensor plantar responses. Lumbar puncture yielded conspicuously xanthochromic fluid under a pressure of 300 mm. of cerebrospinal fluid. Cerebral arteriography disclosed the presence of a subdural hematoma on the right side. Evacuation of the hematoma was followed by recovery.

Reminiscent of the situation often seen at the other extreme of life is a simple failure to thrive, physically and mentally, because of a subdural hematoma.

Case 4.—The patient was a 78-year-old man who had been sent to a nursing home by his family because of near starvation and from the nursing home to the hospital because of progressive deterioration in his nutritional state. At the time of admission, the patient was cachectic, lethargic, and irritable, but he displayed no focal neurological disturbance. In the hospital, he was investigated thoroughly, but no specific reason for his decline could be established. Throughout his 11 weeks in the hospital, and despite vigorous and conscientious medical management, he failed to improve. Finally he became even less responsive, developed cyclic breathing, and shortly thereafter died. Postmortem examination showed bilateral chronic subdural hematomas and pulmonary infarction.

Comment

Clinical Features.—The present study was undertaken with the hope of clarifying the clinical features of subdural hematomas in elderly persons and thereby making it possible to distinguish the disease from others producing similar manifestations. Unfortunately, this objective was not wholly attained, since elderly patients with this malady proved not to present consistently characteristic pictures. None the less, it has been possible to define a variety of clinical situations sometimes associated with this disease.

The first such situation is one in which there is a definite initiating injury, as from a serious fall, automobile accident, or an assault. The patient tends not to improve but may do so slowly and incompletely. He may remain or become confused, demented, or somnolent and develop signs of neurological deficit. In such cases, a surgical lesion can be usually diagnosed with relative ease, and surgical exploration or angiographic study can be used with but slight hesitation. There are, however, patients in whom the clinical course, even after a definite initiating injury, has so much of the flavor of cerebral vascular disease that the suspicion of subdural hemorrhage is not entertained.

A second situation (and it is the one which involved the majority of our patients) is one in which a history of trauma is sometimes not elicited or is denied. If remembered, injury has been considered to be trivial, and one or several minor falls have been interpreted as symptoms rather than causes of the patient's illness. The patient, often too confused to give a reliable history, is frequently sufficiently well enough preserved to give a misleading one. Under such circumstances, he may be admitted to almost any service in the hospital for treatment of his accepted senility plus his "stroke," his pulmonary disease, his heart failure, or other obvious physical disability. Later in his hospital course, he declines more or less markedly and rapidly to become somnolent or comatose. Carefully examined, he usually will be found to have bruises of the scalp, sometimes indistinct and fading, often concealed beneath the hair. Although by no means constant findings, there may be such neurological abnormalities as a hemiparesis with single or double extensor toe signs.

Guillaume and Œconomas,[1a] describing their observations of patients of this category, state that ordinarily they exhibit asthenia, headache (constant or varying with postural changes), diminished intellectual activity, loss of initiative and of memory, and poverty of ideation. More recently, Bedford [1b] has made the following observation:

> Typically the history is that the old person, already somewhat enfeebled, has recently become mentally confused: medical advice or admission to hospital is sought for this latter symptom. A history of a fall within the preceding weeks or months may be elicted—usually by direct questioning—and has been attributed to "old age" or to a "little stroke." The fall may have been accompanied by transient unconsciousness or epileptiform jactitations (and it may be observed here that although a fit is only rarely a symptom of subdural hematoma, it is by no means a rare cause of the fall which leads to the blow on the head—trivial or otherwise—which is its almost invariable antecedent). Physical examination only rarely contributes substantially to the diagnosis. The usual clinical picture is that of a mentally confused old person with some impairment of intellectual capacity (which may be slight, moderate, or profound), who may be somewhat or deeply drowsy—but is as often not—and who may or may not have bruising about the eyes and forehead: there is often evidence of damage to the pyramidal systems, and occasionally pupillary abnormalities not unjustifiably attributable to ocular disease, which also hinders adequate retinoscopy. Very often, too concomitant disease of other systems—a fractured neck of femur, bronchopneumonia, heart failure, or uremia—provides further diagnostic distraction.

Less commonplace clinical situations are exemplified by the case reports of patients who simply failed to thrive, mentally and physically, or who complained early of insistent and severe headaches but showed no physical signs.

Diagnosis.—Bedford [1b] pointed out the difficulty and complexity of diagnosis by noting that fully 80% of 5,000 elderly people admitted to the Oxford Geriatric Unit over an eight-year period were confused—no matter what the diagnosis. His experience with x-rays of the skull and with lumbar puncture resembles ours. Similarly, his diagnostic accuracy approximates our own. In this regard he says: "Indeed, despite the utmost vigilance, only 40% of my elderly cases were diagnosed in life. . . ."

On the other hand, we fail to share the misgivings reflected in his statement that: "It must reluctantly be admitted, therefore, regarding the diagnosis of subdural hematoma in the aged, that unless thousands of old people are to be submitted needlessly to an unjustifiable intracranial exploration, every physician concerned in their care will see a number of patients each year in whom the condition unavoidably defies detection, and this unsatisfactory state of affairs is not materially improved by the knowledge that even without surgery, these effusions are not invariably lethal." Our point of view on this score is based on the fact that of our 20 most recent cases, 19 were recognized in life, admittedly while a certain number of fruitless (but by no means unjustifiable) diagnostic procedures were made in patients without such disease.

Finally, it seems prudent to stress the importance of early diagnosis, if diagnosis is to be made in a living patient and if treatment is to be effectual. Time and again we have encountered instances of sudden and unexpected death caused by subdural collections. Furthermore, the beneficial diagnoses were made early, and treatment too long delayed commonly failed.

Frequency.—From our data, we cannot estimate the actual incidence of subdural hematomas in the aged. Bedford,[1b] however, found the disease in 1% of a rather large group of hospitalized patients over 65 years of age.

Treatment.—Our own proportion of unfavorable results of treatment makes us hesitant to defend any particular method of management. In our cases, liquid clots were drained between bur-holes, and the occasional solid clot required a larger bony opening for its removal. During the past two or three years, we have made it a matter of policy to reoperate on any patient who declined anew after surgery or who failed to rally as expected. In certain instances we have reoperated as many as four times to be gratified, eventually, by the patient's recovery. Our experience with LaLonde's and Gardner's[4] method of spinal injection of saline solution is not extensive enough to allow us to form an opinion about its merits. From the limited use that we have made of this maneuver, we are certain, however, that it does not always make subsequent operations unnecessary.

Summary

In the elderly person, subdural hematoma is a subtle disease frequently disguised so that it may be taken for senile degeneration of the brain, cerebral vascular disease, or other conditions. Although early diagnosis is difficult, it is essential; first, because the clinical course of a patient with a subdural hematoma frequently is terminated abruptly by sudden and unexpected death and, second, because treatment too long delayed often fails.

Despite the lack of an easy solution to this problem, our experience suggests that it may be possible to improve this difficult state of affairs by cultivating an attitude of suspicion and by readily resorting to angiography or exploration in the older patient when the diagnosis can reasonably be entertained.

TRAINING FOR ESCAPE FROM A SUBMARINE.—In water-filled towers 120 feet high, all submarine personnel undergo regular training in a method of individual escape from a disabled submarine. This training, known as bouyant-assisted ascent, is conducted at increasing depths down to 100 feet. In principle, the method is simple: the trainee, wearing an expanded life jacket, steps out of a pressurized lock into the interior of the column of water where he is held on a platform by two instructors. On a signal from one instructor, the trainee forcibly expels the air from his lungs until he approaches residual lung volume. At this point he is released and rises to the surface at a rate of 300 feet per minute. Throughout the ascent the trainee must continue to blow out air, since the compressed residual air in his chest expands rapidly in accordance with Boyle's Law and can produce over distention of the alveolar structures, resulting in massive arterial air embolism. It is because of this potentially fatal hazard that the Submarine Medical Officer must be in constant attendance, working in the water with the instructors during escape training. In the event of a casualty, the doctor and victim are in a topside recompression chamber and at a treatment pressure of about eighty pounds per square inch within ninety seconds after the accident. This pressure reduces the volume of the air emboli that have flooded the left heart, coronaries, aorta, and cerebral vessels, permitting a resumption of blood flow and survival of the stricken individual, in most cases. . . . Aside from its value as an escape training device, the tank serves as a research medium in which a wealth of data on respiratory physiology is constantly being accumulated by our submarine doctors.—Rear Adm. B. W. Hogan. M.C., Surgeon General, U.S.N. The Practice of Submarine Medicine, *Medical Arts & Sciences*, Second Quarter, 1958.

CLINICAL NOTES

IMPORTANCE OF AUTOPSIES—AN ILLUSTRATIVE CASE

Jack Marks, M.D., Columbus, Ohio
and
Kenneth L. Gerson, M.D., Cleveland

The autopsy examination is sought for a variety of reasons, including augmentation of medical knowledge, clarification of cause of death for medicolegal reasons, and the disclosure of hereditary and infectious disease that might have valuable bearing on survivors.[1] Many of these reasons, however, represent abstractions to next of kin and make no real impression on them.[2] We wish to present an instance wherein the information obtained from an autopsy examination was of critical importance to a family member and may be instrumental in the prolongation of life.

Report of a Case

Our patient was a 15-year-old male initially seen in the outpatient department of the Ohio State University Hospital on Feb. 10, 1958, because of a chest deformity noted at the time of birth and of the type similar to that of the patient's deceased father. He had no symptoms of illness and had experienced no disability whatever with his deformity. He had no particular embarrassment over his chest deformity and enjoyed basketball and other vigorous sports. The patient's medical history included surgical repair of a scrotal varicocele at age 5 and trauma to the right eye, which left a residual coloboma of the iris.

On physical examination, our patient was a thin, tall, white male with a chest deformity of the pectus carinatum type. His height was 73 in. (185.4 cm.), the measurement from pubis to heel was 42 in. (106.7 cm.), measurement from pubis to vertex was 31 in. (73.7 cm.), and the arm span was 75 in. (190.5 cm.). His weight was 126 lb. (57.2 kg.). Blood pressure was 110/68 mm. Hg in both arms. Pertinent physical findings included elongated auricular pinnae and a post-traumatic coloboma of the right iris, with the remainder of the ocular examination thought to have been normal. The palate appeared rather high and arched in character. There was an asymmetrical anterior bulging of the left side of the thorax. The extremities showed marked symmetrical elongation of the long bones of the fingers and toes. The joints of the fingers were somewhat hyperextensible; other joints seemed normal. There were high metatarsal arches bilaterally.

Laboratory data were normal with the exception of an elevated alkaline phosphatase level of 36.5 units, for which no explanation was obtained. The 17-ketosteroid and 17-hydroxycorticosteroid levels were normal. X-rays of the skull were reported normal. A chest x-ray showed anterior bowing of the sternum. The cardiac shadow and aorta were thought to be within normal limits. X-rays of the hands and feet were remarkable only in the length of the metatarsal and phalangeal bones. An electrocardiogram was normal.

The patient has two siblings, a 17-year-old brother and a 14-year-old sister, neither of whom had been known to have any illness or deformities. The father had died at age 33 in congestive heart failure with a final clinical diagnosis of rheumatic heart disease and possible subacute bacterial endocarditis. He had had six siblings, of whom all are living and well with no known abnormalities. The paternal grandparents lived long lives, and no abnormalities were known in them.

Transcripts of the father's records and slides of specimens obtained at autopsy were sent us from another hospital. It was learned that eight years prior to his death the father had been hospitalized and discharged with diagnoses of psychoneurosis, anxiety-hysteria in type; partial dislocation of the lenses, O. U.; vitreous opacities, O. U.; congenital punctate cataract, O. U.; and tremulous iris, O. U.

Diagnoses at autopsy were given, in part, as follows: old and recent myocardial infarction; nonspecific interstitial myocarditis; left ventricular hypertrophy and dilatation; marginal aortic valvulitis; and sacular aneurysmal dilatation of the ascending aorta and of the first portion of the arch of the aorta. Microscopic examination of the aorta showed medionecrosis with hyaline and mucoid transformation and interruption of the elastic laminae.

Review of the sections from the father's autopsy at the Ohio State University Health Center showed lesions in the heart and aorta as described above. These findings are identical with the changes of Erdheim's medionecrosis which are described in Marfan's syndrome.[2A] On the basis of the above, we concluded that the patient's father had had Marfan's syndrome, as did our patient.

Comment

Marfan's syndrome is an inheritable disorder probably transmitted by a single dominant autosomal gene. It has been thought to cause changes in structures derived from the mesoderm. These defects can be grouped into skeletal, cardiovascular, and ocular manifestations.

Clinical Instructor in Medicine, the Ohio State University Health Center (Dr. Marks), and Intern, Mount Sinai Hospital (Dr. Gerson).

The skeletal changes are characterized by gracile body habitus (dolichomorphism) with striking elongation of the distal bones of the extremities (arachnodactyly). Patients with this syndrome are usually tall with characteristic alterations of the proportions of the body. Typically the pubis to heel measurement exceeds the pubis to vertex measurement and the arm span is greater than the height. Involvement of the calvarium results in a long appearance of the skull (dolichocephaly). Associated changes of the skull are highly arched palate and long narrow faces. Cleft palate is a rare finding.[3]

The rib cage is frequently involved and results in a funnel-shaped chest (pectus excavatum), pigeon breast chest (pectus carinatum), or other asymmetrical chest deformities. A weakness of ligaments, tendons, fascia, and joint capsules results in hyperextensibility and recurrent dislocations of joints, pes planus, pes cavus, genu recurvatum, and hernias. Ectopia lentis, almost always bilateral, is found in 50 to 80% of the reported cases. The lens is usually small, spherical, and displaced upward. Myopia is frequent, due to excessive length of the eyeball. Retinal detachments occur frequently. Iritis and glaucoma resulting from the displaced lens may be responsible for limitation of vision or even total blindness.

The cardiocascular system is diffusely involved. Aortic insufficiency results in left ventricular hypertrophy. Diffuse interstitial myocardial changes have been described.[4] Marginal valvular thickenings have been noted, and these can be readily differentiated microscopically from those of rheumatic endocarditis. Dilatation of the ascending aorta and aneurysm are frequently noted. Dissecting aneurysm may occur as an initial sign or may follow aortic insufficiency. Defects in the pulmonary artery and the innominate and carotid arteries are less commonly seen.[5] Weakness in the walls of the veins, apparently similar to that in the arteries, may result in varicose veins.[6]

Other aspects of the disorder have been described,[7] including muscular underdevelopment and hypotonia. Deafness is reported[8] to occur in 6% of the cases. Pulmonary malformations and cystic disease of the lung have been thought to be a component of the disease. McKusick[9] has published a comprehensive study of Marfan's syndrome.

In the papers of Griffin and Koman[10] and Marvel and Genovese,[11] a total of 55 cases of Marfan's syndrome were collected, with 48 patients surviving the first year of life. Of these, there was a range of life span of 1 to 55 years and a mean life span of 27.5 years.

Wilson[2A] has recently described three generations of a family affected with Marfan's syndrome. He stated that the degree of physical activity of the individual probably is important in determining the rate at which aortic dilatation occurs. He cited a patient who led a quiet life and felt that the patient's sedentary existence had probably contributed to a prolonged life span.

We therefore counseled the parent to have our patient desist from vigorous athletic competition. We suggested that he be given a type of education preparatory for sedentary work. The significance of this disease with relation to marriage and child bearing was discussed. The counsel given the parent most certainly involves a major alteration to the patient's manner of living and might not have been justifiable without verification of the diagnosis of Marfan's syndrome.

Summary

House officers are frequently faced with the responsibility of requesting autopsy permission from next of kin. Often resistance is encountered for a variety of reasons, some of which are religious, some superstitious, and some simply based on a morbid displeasure of the concept of the autopsy examination. Too often the reasons set forth by the physician to next of kin represent abstract ideas with no apparent immediate benefit for the surviving family. We have found an instance in which information obtained from the autopsy of a father may prolong the life of his son. We believe this case to represent a valuable instance for house officers to draw on in their discussions concerning permission for autopsy with families of their deceased patients.

2620 Schaaf Dr. (9) (Dr. Marks).

SPECIAL REPORT

FEDERAL MEDICAL-HEALTH SPENDING FOR FISCAL YEAR 1959 (JULY 1, 1958, TO JUNE 30, 1959)

The federal government's medical activities are on a massive scale and they continue to grow. This year for all health programs (research, medical care, public health) Uncle Sam is spending about 62.6% more than he did five years ago, 13.5% more than last year. Programs in 22 separate agencies and departments of government range from cancer research to federal employee clinics. The total cost is 2.8 billion dollars, or 344.7 million dollars more than last year. Right now the agencies and the Bureau of the Budget are working on requests to be presented to Congress in January. There is little question that the bills, when finally enacted next year, will set another new high for medical spending.

For six years now the Washington Office of the American Medical Association, through this annual budget report, has charted this expanding course of federal medical activity, a service not performed by any other organization. We identify all programs, describe their purpose, give their present appropriations, and note the amount of increase. We do not attempt to evaluate them—to rate them as good, bad, or indifferent; as wasteful or invaluable. This is a factual study, based on scrutiny of appropriation acts passed by the last Congress and information supplied us by program and fiscal officers in the various departments and agencies, all of whom gave us their wholehearted cooperation. It covers the current fiscal year which ends next June 30.

TABLE 1.—*Medical-Health Budgets of Federal Departments, Agencies, and Commissions for This Fiscal Year*

Agency	Fiscal 1959	Fiscal 1958	Page
Department of Health, Education, and Welfare	$1,116,207,806	$849,395,800	3-10
Veterans Administration	843,524,000	849,374,000	10-11
Department of Defense	751,115,000	702,305,000	12
Atomic Energy Commission	45,462,000	40,085,000	13
International Cooperation Admin.	39,600,000	37,300,000	13
Department of State	21,638,380	15,718,110	13-14
National Science Foundation	19,575,000	7,500,000	14
Office of Civil and Defense Mobilization	13,617,000	3,177,000*	15
Federal Employees Health Programs	11,000,000	10,000,000	15
Department of Labor	8,827,000	8,069,476	15
Panama Canal Co. and Panama Canal Zone Government	3,959,900	5,988,300	16
Department of Treasury	3,854,500	3,837,850	16
Department of Justice	2,105,000	1,796,000	16
District of Columbia	2,000,000	3,700,000	17
Federal Trade Commission	1,600,000	1,500,000	17
Department of Commerce	1,212,400	911,300	17-18
Civil Service Commission	426,000	387,000	18
President's Comm. for Employment of the Physically Handicapped	214,700	182,575	18
Small Business Administration	150,000	70,000	18
Department of the Interior	140,000	154,950	19
National Advisory Committee to Selective Service	19,000	19,000	19
Office of the Attending Physician of Congress	13,145	12,145	19
Totals	$2,886,260,831	$2,541,483,506	

* The figure for fiscal 1958 is the appropriations of the Federal Civil Defense Administration and the Office of Defense Mobilization; now combined in the Office of Civil and Defense Mobilization.

While nearly 38 million people are eligible to receive all or part of their medical care from or through the federal government, medical care represents only a part of the total spent by the U. S. in medical fields. Many millions of dollars go for research, drug control, personnel training and other efforts not directly related to the rendition of medical care.

As in last year's report, we have listed in table form payments to disabled persons through programs which the federal government finances entirely or in part. Such beneficiaries now total nearly 6,000,000, a 15% increase over last year. Money paid them has increased to 4.75 billion dollars, over 40% more than last year. These data are on the last page, separated from the rest of the report because not all of the money is federal.

DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE (This Year: $1,116,207,896—Last Year $849,395,800)

Division of Hospital Facilities....................$187,800,000
last year: $122,650,000

This division administers the federal aspects of both the original and expanded Hill-Burton programs. In 1958 Congress enacted legislation which authorizes loans in lieu of grants for any of the eligible projects under the entire program. Since 1946 the federal contribution through June 30, 1958, amounts to $1,024,000,000; when the sponsors' share is included, the total is $3,323,000,000 (these figures are for both the original and the expanded program). This is the first time since fiscal 1950 that the appropriation has reached $150,000,000 for the original program plus the categorical programs. Total appropriations are divided into the following four categories:

Hill-Burton Original Program....................$150,000,000
last year: $ 99,000,000

This appropriation, allotted to the states on the basis of population and per capita income, assists in the financing of new hospitals and related health facilities construction under the original Hill-Burton program. To June 30, 1958, federal funds have partially financed approximately 3,476 projects, including 159,745 hospital beds, 768 public health centers, 23 state health laboratories and something in excess of 100 nurses' homes and training facilities.

Medical Facilities—Category Program....................$35,000,000
last year: $21,000,000

The total allotted to the state this year on a population-per capita-income formula will assist in the financing of new construction under the 1954 amendments in four categories as follows: $7,500,000 for hospitals for the chronically ill and impaired; $7,500,000 for diagnostic centers, or diagnostic and treatment centers; $10,000,000 for nursing homes; and $10,000,000 for rehabilitation facilities. As under the original program, the federal share may range from one-third to two-thirds of the total project cost. As of June 30, 1958, a total of 496 projects had been approved, divided among the four categories as follows: facilities for chronically ill (98), diagnostic-treatment centers (196), nursing homes (125), and rehabilitation facilities (82).

Hill-Burton Administrative Expenses....................$1,600,000
last year: $1,450,000

This appropriation is used for administration, including salaries and expenses for the hospital survey and construction program for the federal headquarters and for eight regional federal offices.

Research $1,200,000
last year: $1,200,000

Authorized in 1949 but not appropriated until 1955 is this item for research, experiments and demonstrations on utilization of hospital services, facilities and resources. The bulk of the money is assigned as grants to states, universities, hospitals, hospital associations, professional associations, and community organizations and a small amount for direct research by U. S. Public Health Service.

National Institutes of Health....................$324,383,000
last year: $241,183,000

National Cancer Institute....................$75,268,000
last year: $56,402,000

About 50% of this appropriation is earmarked for grants to non-federal individual investigators and private institution for research and training. Almost 25% will be used to support contracts with the pharmaceutical and chemical industries in research on chemotherapeutic agents for the treatment of cancer. The states receive $2,250,000 for cancer

---

This report was prepared by the Washington Office of the American Medical Association.

control work. $4,212,000 will provide professional and technical assistance to public and private institutions engaged in prevention, diagnosis, and treatment among individuals and large population groups (cytology activities) and environmental cancer activities. The balance is for direct research operations, including salaries, supplies, and this Institute's share in the cost of operating the Bethesda (Md.) Clinical Center and related auxiliary services.

National Heart Institute..$45,613,000
last year: $35,936,000

Grants to non-federal individual investigators and public and private institutions for research and training take about 75% of the appropriation. $2,125,000 is allocated to states for heart disease control. The balance is for direct research operations, including salaries, supplies, and this Institute's share in the cost of operating the Bethesda (Md.) Clinical Center and related auxiliary services.

Mental Health Institute..$52,419,000
last year: $39,217,000

Approximately 75% of this appropriation is apportioned for research and training through grants to individual investigators and public and private institutions. The sum of $4,000,000 is allocated to the states for community mental health services. The remainder is for direct research operations, including salaries, supplies, and this Institute's share in the cost of operating the Bethesda Clinical Center and related auxiliary services.

Arthritis & Metabolic Diseases Institute...............$31,215,000
last year: $20,385,000

Grants to public and private investigators for research and training total 75% of this appropriation. The balance is for direct research operations, including salaries, supplies and this Institute's share in the cost of operating the Bethesda Clinical Center and related auxiliary services.

Neurological Diseases & Blindness Institute..........$29,403,000
last year: $21,387,000

Grants to public and private investigators and institutions for research and training total 80% of this appropriation. The remainder is for direct research operations, including salaries, supplies, and this Institute's share in the cost of operating the Bethesda Clinical Center and related auxiliary services.

Allergy & Infectious Diseases Institute.................$24,071,000
last year: $17,400,000

Research grants to public and private investigators for research and training amount to 70% of this appropriation. The remainder is for direct research operations, including salaries, supplies and this Institute's share in the cost of operating the Bethesda Clinical Center and related auxiliary services.

Dental Health Institute..$7,420,000
last year: $6,430,000

Grants to public and private investigators for research and training total about 60% of this appropriation. $983,000 will be used for technical assistance to states and $320,000 for coordination and development of dental resources. The remainder is for direct research at Bethesda, review and approval of grants, administrative expenses, and for support of the Clinical Center.

National Institutes of Health—General Funds......$28,974,000
last year: $14,026,000

These funds are administered by the Division of General Medical Science of the National Institutes of Health, with practically all funds being expended for research and training grants, with the exception of $2,236,000 for control of biologics (including polio and flu vaccine), which activity is under the Division of Biologics Standards. The balance goes toward supporting fellowships and administrative expenses relating to grants.

Laboratory Research Construction (NIH)...........$30,000,000
last year: $30,000,000

There is available for planning and construction of research facilities $30,000,000 the authority for which is Public Law 835 (84th Cong.). To be eligible for grants, the applicant must be a public or nonprofit institution determined by the Surgeon General, after consultation with the National Advisory Council on Health Research Facilities, to be competent to engage in the type of research for which the facility is to be constructed. This is the third year of this program's operation.

Water Pollution Control..$45,000,000
last year: $47,500,000

Under Public Law 660, enacted in 1956, the Federal Government makes grants for the construction of waste treatment plants. Although $45,000,000 was appropriated for fiscal 1959, the funds allocated to the states will be based on the $50,000,000 authorized in the basic legislation.

Hospitals and Medical Care.................................$48,454,000
last year: $44,399,000

These funds are used for operational costs and maintenance of PHS hospitals and health services in caring for American seamen, Coast Guard and Public Health Service personnel and their dependents, federal employees injured at work, leprosy patients and narcotic addicts, and includes studies in the development and coordination of nursing resources. It also includes $1,000,000 for payments to Hawaii for care of patients suffering from leprosy and $5,800,000 for nurse training grants. Not shown in the appropriation is approximately $4,500,000 additional income, principally from other federal agencies for reimbursable services.

Indian Health Activities..$44,597,000
last year: $43,230,300

Under Public Law 568 (83rd Cong.), PHS assumed responsibility for the health of American Indians and natives of Alaska which formerly was a function of Interior Department. The total is broken down as follows: hospital care in Indian hospitals, $23,756,000; contract patient care, $8,000,000; field health services $6,620,000; program direction and management services, $2,097,000; and modernization of hospitals and construction of facilities $4,124,000. In addition, the Indian health activities of PHS will receive approximately $740,000 as reimbursements from other governmental agencies for services rendered in PHS facilities.

Assistance to States—General................................$22,889,000
last year: $22,592,000

Grants totaling $15,000,000 will be available for allocation to the states in support of state and local general public health activities. These grants must be matched one state dollar for every two federal dollars. U. S. Public Health Service will spend $5,889,000 to provide technical assistance, consulting services to states, expenses of the National Office of Vital Statistics, international health activities, demonstrations, training activities, and operational expenses. A total of $2,000,000 will be available for grants to schools or direct traineeship awards to individuals for the training of professional public health personnel.

Sanitary Engineering Activities............................$12,815,000
last year: $12,640,000

This program is made up of seven activities as follows: air pollution control, $3,860,000; water supply and water pollution control, $6,600,000; radiological health activities, $608,000; milk and food sanitation activities, $492,000; interstate carrier and general sanitation activities, $510,000; Sanitary Engineering Center research activities, $440,000; and administration, $305,000.

Tuberculosis Control...$6,386,000
last year: $7,000,000

Grants to states for diagnostic and treatment clinics, mass case-finding and follow-up services account for $4,000,000, all of which has to be matched equally by the states. The remainder is for direct operations of PHS.

Communicable Disease Activities............................$8,300,000
last year: $6,250,000

The entire appropriation is used for direct activities of the PHS Communicable Disease Center at Atlanta, Ga., and its affiliated operations. The Center carries on studies in epidemiology, furnishes laboratory diagnostic services and sponsors special projects to assist states. This amount includes $1,700,000 for equipment for the new Communicable Disease Center which is now under construction in Atlanta.

Office of the Surgeon General..................................$5,260,000
last year: $5,100,000

For administrative expenses of this office, including all housekeeping services, evaluation of public health needs, and personnel training. Included also is approximately $1,389,400 for administration of the National Health Survey Act authorized by Public Law 652 (84th Cong.).

Venereal Disease Control...$5,400,000
last year: $4,415,000

Of the total, $2,400,000 goes for direct grants to states for venereal disease detection, treatment and control on a special-need basis. Most of the remainder is spent for technical assistance to the states, including funds to pay 258 federal employees, the majority of whom are assigned to state health departments.

Foreign Quarantine Service...................................$4,108,000
last year: $3,876,000

This service operates 310 medical quarantine stations on borders of the United States. It also operates 28 medical examination stations on foreign soil for the examination of aliens seeking visas to enter the U. S. Inspections are made of all seagoing vessels and aircraft entering the U. S. It is estimated that the service will examine more than 3,100,000 aliens in this country and 210,000 abroad.

Alaska Health and Sanitation Programs..................$8,665,000
last year: $2,165,000

This appropriation will be divided as follows: $638,000 for grants to Alaska for public health services; $527,000 for research activities of the Arctic Health Research Center at Anchorage; $1,000,000 to enable Alaska to pay for hospitalization for Alaska's mentally ill at Morningside Hospital in Portland, Oregon; and $6,500,000 for construction of mental health facilities in Alaska as authorized by the Alaska Mental Health Act.

National Library of Medicine.................................$8,365,000
last year: $1,450,000

As a result of Public Law 941 enacted in 1956, the Armed Forces Medical Library was renamed the National Library of Medicine and transferred to the Department of Health, Education, and Welfare. A new structure has been authorized to house the Library and $6,950,000 in construction funds was appropriated for 1959. The new Library will be built on the southeast corner of the NIH reservation at Bethesda.

Reimbursable Health Programs for Other
Governmental Agencies..$487,000
last year: $475,000

This represents the cost of services expected to be advanced to Public Health Service by other governmental agencies for establishing and operating on-the-job clinics. PHS deals largely with Washington personnel, whereas 90% of the total number of government's employees are located outside the greater Washington area.

Freedmen's Hospital..$2,975,000
last year: $3,000,000

This institution with an average patient load of 328, plus 32 new-borns, is a medical teaching facility and general hospital. Its patients are chiefly medical indigents from the District of Columbia and the adjoining area. The hospital is utilized for training of interns and residents, chiefly from Howard University, and it has a nurses' training school. A total of $4,267,000 is authorized for operating costs. All in excess of $2,975,000 (appropriated for fiscal 1959) are expected reimbursements from charges made to patients and payments made by the District of Columbia and other federal agencies and from the counties surrounding Washington who utilize these facilities for welfare patients. Some supervisory functions over this program is vested in PHS.

Howard University...$1,022,000
last year: $1,136,000

This University came into being shortly after the close of the Civil War because of the lack of higher educational facilities for negroes. It is jointly supported by congressional appropriations and private funds and offers instruction in ten schools and colleges, including colleges of medicine, dentistry, and pharmacy. This year the University's total operational budget is in excess of $8,000,000. Of this amount, the Federal Government will contribute $4,350,300 toward operational expenses, $123,000 for plans for construction, and $163,000 for completion of a men's dormitory. The combined budgets for the colleges of medicine, dentistry, and pharmacy will require approximately 24% of the University's total budget. The entire student body of the University for 1958-59 will be approximately 5,500. There are 350 students enrolled in the college of medicine, 289 in the college of dentistry and 133 in the college of pharmacy. The federal contribution for direct current operations in the colleges of medicine, dentistry, and pharmacy total approximately $1,022,000, according to the University's treasurer.

St. Elizabeths Hospital...$17,082,000
last year: $15,904,500

St. Elizabeths provides treatment for several classes of mentally ill persons, including those residing in the District of Columbia, beneficiaries of the Veterans' Administration, beneficiaries of Public Health Service, insane persons charged with or convicted of crimes in U. S. courts (including the Court of the District of Columbia), certain American citizens found insane in Canada, the Panama Canal Zone and the Virgin Islands, certain foreign service personnel, and members of the military services admitted to the hospital prior to July 16, 1946. Congress appropriated $3,186,000 to this institution for operational expenses $87,000 for major repairs, and $125,000 for construction planning. Reimbursements from other agencies will approximate $13,684,000. This hospital has an average daily patient load of 7,000.

Bureau of Public Assistance (Medical
Payments) $240,000,000
last year: $150,000,000

Out of a total budget of approximately $3.2 billion (federal and state) for categorical public assistance programs, officials of the Social Security Administration estimate that approximately 12.8% is now being devoted to health care of recipients. For all facets of living expenses and medical care, the total federal contribution this year will be about $1.9 billion. An estimated $410 million of federal, state, and local funds are expected to be paid for medical and health needs of categorical assistance recipients this fiscal year. About $330 million will be paid to vendors of medical care, such as physicians, hospitals, pharmacists, nursing homes, etc., and about $80 million directly to recipients to enable them to meet their medical care needs. The federal share of combined medical payments to vendors and to recipients will be about $240 million.

Office of Vocational Rehabilitation.......................$57,800,000
last year: $50,830,000

Under the expanded Vocational Rehabilitation Act (Public Law 565, 83rd Cong.), Congress this year appropriated $56,400,000 for grants to states and other agencies. This is divided as follows: (a) support of basic rehabilitation services, including medical examinations, surgical and therapeutic treatment, hospitalization, prostheses, occupational tools and aids, vending stands, rehabilitation facilities, vocational training and funds for maintenance (based on per capital income and population as in Hill-Burton), $45,500,000; (b) extension and improvement of state programs, $1,500,000; (c) special grants to states or nonprofit organizations for projects designed to expand the rehabilitation program (2-1 federal-state matching), $4,600,000; (d) $4,800,000 for training of rehabilitation personnel, including physicians, therapists, psychologists, counselors, medical and psychiatric social workers. In addition $1,400,000 is available for federal administrative costs.

Children's Bureau $32,300,000
last year: $32,300,000

Operating under the Social Security Administration, the Children's Bureau administers grants to states for maternal and child health, and crippled children's and child welfare services. This year grant money totals $43,500,000 divided as follows: $16,500,000 for maternal and child health work; $15,000,000 for crippled children's services; and $12,000,000 for child welfare services. However, this last item has no medical significance and, therefore, it is not reflected in the total of $32,300,000. One-half of the federal funds for maternal and child health and crippled children's services is required to be matched dollar for dollar by the states. In addition the Children's Bureau has $2,000,000 to finance investigating and reporting activities and to administer all the grants. About 40% of this amount is chargeable to the health and related activities of the Children's Bureau which include administration of grants for maternal and child health and crippled children's services and consultative services to state agencies and other public and voluntary agencies and organizations engaged in the provision of maternal and child health services.

Federal Surplus Property
Donation Program...............................Approx. $18,319,806
last year: $15,200,000

The Department of HEW has authority to make donations of personal property and transfer of real estate declared surplus by federal agencies for health needs. In the case of real estate, conditional title is vested in the transferee and then after a number of years of utilization of the property in accordance with imposed conditions the property can become absolutely vested. Recipients of personal property may be medical institutions, health centers, hospitals and clinics. Eligible donees of real property may be any institutions organized for health purposes, including those engaging in medical research. It is difficult to determine the exact value of property donated and transferred since accounting is on the basis of acquisition cost. Last year approximately $60,910,000 of personal property (acquisition value) was allocated for health purposes which probably had a fair market value of roughly $18,000,000. During the same period, approximately $1,229,582 of real estate (acquisition value) was transferred with a fair market value of $319,806. It is expected that the level of donations and transfers for the current fiscal year will be in line or slightly in excess of last year's totals.

Food and Drug Administration..............................$9,800,000
last year: $9,300,000

For administering the Food, Drug and Cosmetic Act, Congress voted the above funds. FDA will also realize an estimated $1,410,000 from fees paid by industry for certification of antibiotics, insulin, etc.

U. S. Office of Education..$4,000,000
last year: $4,000,000

For a number of years the Office of Education has been making grants to states chiefly for vocational education. During the last fiscal year approximately $4,000,000 was made available as grants to aid the states in the training of practical nurses. For this year, the Office of Education has available approximately $34,000,000 for grants to states, of which $4,000,000 is again earmarked for the practical nurse training program.

VETERANS ADMINISTRATION

(This Year: $843,524,000–Last Year: $849,374,000)

In-Patient Care in VA Hospitals*.....................$675,298,000
last year: $657,071,000

VA's largest single medical expenditure covers in-patient care in 173 VA hospitals and provides for an estimated 120,954 beds. At present VA reports an estimated daily patient load of 111,063, approximately 92% of bed capacity. The appropriation includes salaries of physicians and other personnel, medical rehabilitation of veterans, dietetic and nursing services, social services and special services, such as recreation and transportation of veterans.

Out-Patient Care* $75,399,000
last year: $79,000,000

The bulk of this appropriation is for out-patient care in about 100 VA clinics. The remainder is earmarked for fees to physicians ($8,079,000) and dentists ($1,048,000) under the home-town care program.

Modernization and Replacement Construction*....$16,595,000
last year: $42,500,000

This amount is for work on existing units where costs exceed $300,000 per project and equipment for new units. The money is available until expended. (See Alterations and Improvements item on this page for small projects.)

Domiciliary Care*..$31,812,000
last year: $31,490,000

Domiciliary care is being provided in 17 VA facilities for about 16,810 veterans who, while incapacitated for employment, are not in need of full hospital care. VA also makes payments to 33 state veterans homes with a daily patient load of approximately 9,500. Payments this fiscal year are estimated at $6,440,000. Under Public Law 613 (83rd Congress) federal contributions to these homes were raised from a maximum of $500 to $700 a year per patient.

Contract Hospitalization*.....................................$13,557,000
last year: $13,389,000

This appropriation finances an average daily patient load of 3,117 veterans in federal hospitals other than VA and in state and municipal hospitals. Patients in federal non-VA hospitals are estimated at 1,324 and in non-federal hospitals, 1,676. Mental cases make up the largest single category of contract cases.

Medical Administration*..$7,175,000
last year: $7,862,000

To operate the VA Department of Medicine and Surgery in the central office and the seven area medical offices; included are salaries, travel and like expenses.

Medical Research*................ ....$16,344,000
last year: $11,344,000

For research, mostly in VA hospitals. The breakdown: general medical and surgical research, $9,600,700; atomic medical research, $2,803,300; prosthetics testing, $1,000,000; neuropsychiatric, $1,659,100; tuberculosis, $1,130,900; other, $150,000.

Alterations, Improvements and Repairs*................$2,700,000
last year: $2,028,000

For alterations, improvements and repairs to VA clinics and domiciliaries (costing less than $300,000 per project).

Supply Depot Operations*.....................................$2,055,000
last year: $1,790,000

For maintaining and operating supply depots handling the purchase, shipping and storage of medical supplies and equipment used by the Department of Medicine and Surgery.

Medical Education and Training*..........................$1,339,000
last year: $1,400,000

For VA training programs for physicians and other VA personnel in medical specialties and auxiliary services.

---

*In appropriating for VA, Congress stipulated that the funds were predicated on furnishing care and treatment for 140,490 beneficiaries during this year. This total of beneficiaries was arrived at by adding the estimated number of veterans to be cared for in VA hospitals, domiciliary facilities, contract hospitals, and state veterans homes. There is no way of estimating whether more or fewer patients than this total will be cared for during the year. If VA doesn't furnish care at this level, its funds will be reduced proportionately.

Medical Care—Philippine Veterans........................$1,250,000
last year: $1,500,000

Until 1960 the U. S. will contribute for the medical care of Philippine veterans.

DEPARTMENT OF DEFENSE

(This Year: Approx. $751,115,000—Last Year: Approx. $702,305,000)

Army Medical Services*......................Approx. $295,000,000
last year: $270,700,000

The estimated cost includes expenses normally associated with the operation of military hospitals and dispensaries, military and civilian salaries, medical supplies and equipment, utilities, communications, transportation travel subsistence, maintenance and repair of buildings and grounds, expenses for construction, dependent medical care, medical education and training, medical research and preventive medicine.

Air Force Medical Services*................Approx. $221,000,000
last year: $211,400,000

The estimated cost includes expenses normally associated with the operation of military hospitals and dispensaries, military and civilian salaries, medical supplies and equipment, utilities, communications, transportation travel subsistence, maintenance and repair of buildings and grounds, expenses for construction, dependent medical care, medical education and training, medical research and preventive medicine.

Naval Medical Services*......................Approx. $235,000,000
last year: $220,100,000

The estimated cost includes expenses normally associated with the operation of military hospitals and dispensaries, military and civilian salaries, medical supplies and equipment, utilities, communications, transportation travel subsistence, maintenance and repair of buildings and grounds, expenses for construction, dependent medical care, medical education and training, medical research and preventive medicine.

Office, Asst. Secretary of Defense
(Health & Medical)................................Approx. $115,000
last year: $105,000

For salaries, travel and administration of this office, and for travel expenses and consultant fees for the Defense Department Civilian Health and Medical Advisory Council.

The 85th Congress placed restrictions on the Dependents Medical Care Program (Medicare). Because of these changes, reliable program cost estimates cannot be made at this time.

ATOMIC ENERGY COMMISSION

(This Year: $45,462,000—Last Year: $40,085,000)

The Atomic Energy Commission's Division of Biology and Medicine has about $5.4 million more than last year for research projects. This year's total includes the following spending plans: cancer, $4,172,000; other medical, $12,268,000; biological, $14,104,000; biophysical, $1,784,000; development of new laboratory equipment, $2,498,000; vocational and special training, $2,220,000; radioisotope distribution, $310,000; environmental science, $5,394,000; and miscellaneous items, $2,712,000.

INTERNATIONAL COOPERATION ADMINISTRATION

(This Year: $39,600,000—Last Year: $37,300,000)

Technical Cooperation Health Programs.............$14,000,000
last year: $14,000,000

The International Cooperation Administration through cooperatively financed programs is helping 44 countries, at their request, to improve their health and living conditions. The broad range of health projects falls into the fields of: (1) epidemic and infectious disease (malaria, trachoma, smallpox, typhoid); (2) environmental sanitation (safe water systems and sewage disposal); (3) development of rural health services and facilities (health centers, hospitals, clinics, laboratories); (4) training of personnel both locally and in the United States; (5) the establishment and development of basic health training institutions (schools of nursing, schools of public health).

Malaria Eradication Program...............................$25,600,000
last year: $23,300,000

In the Mutual Security Act, the 85th Congress authorized U. S. participation in a world-wide malaria eradication program not to exceed the amount indicated above.

DEPARTMENT OF STATE

(This Year: $21,638,380—Last Year: $15,718,110)

United Nations Children's Fund............................$11,000,000
last year: $10,000,000

The United States' share of the Children's Fund is up about $1,000,000 over last year for a total of $11,000,000. The percentage of U. S. contribution to the total fund has dropped slightly from 55% to 52.5%. Other governments increased contributions from $8.2 million last year to $9.9 million this year. There are 81 contributing governments and territories. The fund is aiding 324 health and medical projects in 104 territories and benefiting 50 million children and others. More than 45,000,000 children and pregnant and nursing mothers benefited directly from the Fund last year. More than 14,000,000 children were vaccinated against tuberculosis, some 28,000,000 were protected with DDT against malaria, some 2,800,000 children and mothers were treated for yaws, bejel, or syphilis, 900,000 children were treated for tracoma.

World Health Organization...................................$7,424,380
last year: $4,200,110

This country's share of the WHO budget remains at about one-third of the total assessments of the 85 member governments. Last year WHO was sponsoring about 600 projects in 117 countries and territories. WHO's overall budget is broken down this way: approximately 88% for operating programs, 9% for administration, and the rest for organizational meetings. WHO actually had three appropriations from the U. S. The first is for $4,666,480 for its general activities; the second for $300,000 for research; and the third for $5,000,000 for malaria eradication which will come from ICA's $25,600,000. This organization also administers $5,462,000 obtained from the U. N. technical assistance program. Approximately $2,457,900 of this total comes from the U. S.

Pan American Sanitary Bureau...............................$1,914,000
last year: $1,518,000

The United States is contributing approximately two-thirds of the Bureau's regular budget which this calendar year totals $3,000,000. In addition, this country hopes to allocate $3,000,000 for 1959 malaria eradication programs which will come from ICA's $25,600,000 (see above). The Bureau, in existence many years before WHO was organized, is the regional office of WHO for the Americas. The Bureau is sponsoring health programs in 20 Latin American countries, dependent territories of European powers in this hemisphere, and the United States.

Health Program for Overseas Employees................$1,300,000
(new program)

The Department of State furnishes health care to 10,000 overseas employees and approximately 15,000 of their dependents. In the case of dependents, the government pays for medical care only after the first $35 of expense incurred for a single illness. In most cases, military medical facilities of our government overseas and facilities operated by the United States Public Health Service are utilized. However, in some cases private physicians and private hospitals are used.

---

*A Defense Department source gives this explanation: All dollar amounts are estimates and have been rounded because military appropriations are not broken down into categories of medical expenditures. The estimated increase during fiscal year 1959 in the total military medical programs (about $49 million higher than was estimated in October of 1957 for the fiscal year 1958) is primarily attributable to an increase in the cost of goods and services and because of an increase in salaries for military and civilian personnel, approved in the latter part of fiscal year 1958. It is estimated that the average daily patient load will approximate the same as for fiscal 1958 and that in the combined military services in-patient hospital care this year will cost about $319 million. Out-patient care, which will cost about $171 million because of an estimated 34,000,000 out-patient visits, excluding dental visits, reflects a small reduction in workload due to reduction in military population.

NATIONAL SCIENCE FOUNDATION

(This Year: $19,575,000–Last Year: $7,500,000)

The Foundation's overall budget of $130,000,000 is $90,000,000 above last year's appropriation. The sum of $19,575,000 is earmarked for research grants in the biological and medical sciences. The Foundation provides support for basic scientific research, for training and education in the sciences through fellowships and programs to improve science teaching, and programs to improve exchange of scientific information.

OFFICE OF CIVIL AND DEFENSE MOBILIZATION

(This Year: $13,617,000–Last Year: $3,177,000)

Under Reorganization Plan No. 1 of 1958, the Federal Civil Defense Administration and the Office of Defense Mobilization were consolidated into what is now the Office of Civil and Defense Mobilization. The total budget for this new agency is $45,285,000. The health and medical activities will expend $13,617,000 broken down as follows: salaries and expenses, $403,000; research $179,000; education (medical education for national defense), $135,000; federal medical stockpiling, $12,400,000; federal matching contributions re medical equipment for state agencies, $500,000.

FEDERAL EMPLOYEES HEALTH PROGRAMS

(This Year: $11,000,000–Last Year: $10,000,000)

Another health program, this one available to all federal civilian workers, provides limited services through health clinics. They are operated by federal agencies which employ 300 or more persons in any one area. By regulation, maximum cost of a health service cannot exceed $13 a year per employee, although special industrial conditions or minimal size units may warrant a higher ceiling. Services include treatment for on-the-job illness and physical examinations for employment.

DEPARTMENT OF LABOR

(This Year: $8,827,000–Last Year: $8,069,476)

Bureau of Employees' Compensation......................$8,200,000
last year: $7,500,000

An estimated 2,337,000 federal workers are eligible under the Federal Employees' Compensation Act for medical and hospital care, rehabilitation services, disability and death payments, funeral and burial expenses. For treatment of employees by private doctors and hospitalization in private facilities, the Labor Department has set aside $6,200,000 this fiscal year, and for similar services in federal hospitals and clinics, $2,000,000. Expenditures for care by non-governmental physicians and in private hospitals has been increased by $545,000 over last year's spending level.

Bureau of Labor Standards.......................................$627,000
last year: $569,476

For promotion of industrial safety, the Bureau plans to spend $412,300, and for re-employment programs of the physically handicapped, $214,700. The agency develops standards for hazardous occupations, assists the states in accident prevention programs and assist states and unions in training safety personnel.

PANAMA CANAL COMPANY AND PANAMA CANAL ZONE GOVERNMENT

(This Year: $3,959,900–Last Year: $5,988,300)

Expenditures for fiscal 1959 for operation of Canal Zone hospitals and clinics is estimated at $6,343,800. Medical services are available to Zone employees and their dependents, certain military and other persons. Some of these patients make payments toward the cost of their medical care, which payments are returned to the United States Treasury. In 1959 such revenue is estimated at $3,266,200. When last year's report was compiled, the revenue figure was not obtainable. Expenditures for operating public health activities, including sanitation, health director's office, Division of Veterinary Medicine, preventive medicine and quarantine and general government expense applicable to the Health Bureau, should total $882,300. The four hospitals operated by the Health Bureau of the Canal Zone Government contain 1008 beds as follows: Gorgas Hospital (440), Coco Solo Hospital (148), Corozal (300), Palo Seco Leprosarium (120). In addition there are two dental clinics, one medical clinic and five first-aid stations.

DEPARTMENT OF TREASURY

(This Year: $3,854,500–Last Year: $3,837,850)

The Bureau of Narcotics, operating within the Treasury Department, is primarily engaged in investigation, detection and prevention of violations of the federal narcotic and marihuana laws. Subsidiary functions are: (1) exercising control over the legitimate manufacture and distribution of narcotics within the United States through a quota-system and supervision over approximately 302,000 qualified registrants (physicians, pharmacists, dentists, wholesalers, etc.); and (2) training of narcotics law enforcement officers sponsored by local and state law enforcement agencies. Increased emphasis is being placed on drying up interstate and international sources of illicit supplies.

DEPARTMENT OF JUSTICE

(This Year: $2,105,000–Last Year: $1,796,000)

The figure represents the Bureau of Prisons' estimate of the cost of medical and dental services for approximately 22,000 prisoners in 30 federal penal institutions. The bulk (about $2,000,000) goes to commissioned officers of the Public Health Service assigned to the prisons and to related civil service personnel for services that include psychiatric, medical, surgical, nursing and dental treatment. Another approximately $105,000 is earmarked for fees to 220 consultants in various medical specialties.

DISTRICT OF COLUMBIA

(This Year: $2,000,000–Last Year: $3,700,000)

Only a rough estimation can be made of the federal contribution for health and medical programs of the District of Columbia. The total District budget for all governmental functions is in the neighborhood of $204,000,000. Congress has appropriated $20,000,000 for this year toward the cost of the District government or about one-tenth of the total. The District Health Department will expend $32,605,000. In this amount is included approximately $12,498,000 for care of the District's insane in St. Elizabeths Hospital. Since such sum is shown in this report under St. Elizabeths Hospital, it may be deducted from the District's appropriation for public health, leaving a net balance of $20,107,000 in that category. Since the federal contribution to the District budget represents only one-tenth, then the federal contribution attributable to health and medical activities can be approximated at $2,000,000.

FEDERAL TRADE COMMISSION

(This Year: $1,600,000–Last Year: $1,500,000)

The Commission plans to spend about the same as last year for research, testing and compliance operations in the field of food, drugs, cosmetics and devices. This is nearly 20% of the agency's total budget of $5,975,000. FTC is charged by Congress with the safeguarding of life and health of the public through the prevention of the dissemination of false advertisements of various products.

DEPARTMENT OF COMMERCE

(This Year: $1,212,400–Last Year: $911,300)

Civil Aeronautics Administration...............................$600,000
last year: $385,000

Spending for the Civil Aeronautics Administration flight safety program is divided as follows: $375,000 for salaries and administrative expenses at headquarters; $170,000 for similar expenses in regional offices; $55,000 for the CAA Medical Research Laboratory at Oklahoma City. Five full-time and four part-time medical officers in the field supervise the periodic physical examinations required of commercial and private pilots. CAA has 1,826 designated medical examiners in the United States and overseas. A total of 225,614 examinations were made last year and a similar number are expected to be made this year. For this service, pilots pay examining physicians directly.

National Bureau of Standards..................................$612,400
last year: $526,300

The Bureau of Standards performs tests and engages in developmental research on its own initiative and at the request of others. The Bureau will expend $176,800 of its own money this year as follows: $117,200 for radiation research; $43,000 for audiometric calibrations research; $16,600 for dental materials research. In addition the Bureau will receive $435,600 from other agencies, divided as follows: $71,100 for radiation research; $91,000 for air pollution research; $49,000 for instrument testing; $63,500 for anesthesiological and respiratory equipment evaluation; $93,000 for dental materials research; and $68,000 for preparation of C-14 labeled carbohydrates.

CIVIL SERVICE COMMISSION

(This Year: $426,000–Last Year: $387,000)

The Commission's total budget is approximately $18,200,000, out of which about 2.3% goes to the medical division for salaries of eight physicians in Washington and eleven in the regional offices. The medical division's duties include establishing and reviewing physical standards for all civilian jobs in the Federal Government, supervising and adjudicating disability claims for retirement, and setting professional standards of doctors and ancillary personnel to be employed in government in the competitive civil service.

PRESIDENT'S COMMITTEE FOR EMPLOYMENT OF PHYSICALLY HANDICAPPED

(This Year: $214,700–Last Year: $182,575)

Projected spending is for salaries and administration in the development and promotion of educational programs among employers and the general public to stimulate employment of qualified physically handicapped persons. It also entails expenses in connection with the National Employ the Physically Handicapped Week.

SMALL BUSINESS ADMINISTRATION

(This Year: $150,000–Last Year: $70,000)

The Small Business Administration provides financial assistance to hospitals, convalescent and nursing homes, medical and dental laboratories, and physicians for expenses, improvements and general operations. Small Business Administration loans are of two types: participation loans, those made jointly with banks and other private lending institutions; and direct loans, where no participation is available. Since all loans must be of such sound value or so secured as reasonably to assure repayments, no program losses are anticipated. SBA officials estimate that administrative expenses for the headquarters and field offices will approximate $150,000, which is about 1.5% of the total administrative fund available for all lending operations.

DEPARTMENT OF THE INTERIOR

(This Year: $140,000–Last Year: $154,950)

The Bureau of Mines, operating within the Department of the Interior, has a total appropriation of $5,585,000 for health and safety activities for this fiscal year. Identifiable health programs and expenditures are as follows: $41,000 for a program for silicosis prevention in mines; and $99,000 for studies on natural and equipment fuel gases in mines and effect of radioactivity in metal mines.

NATIONAL ADVISORY COMMITTEE TO SELECTIVE SERVICE

(This Year: $19,000–Last Year: $19,000)

In requesting this budget, which is the same as last year's appropriation, the National Advisory Committee to Selective Service was informed by the military it probably would not be necessary to make draft calls for physicians in the current fiscal year. In any event, if calls were necessary, they would be less than the level which obtained when state and territorial offices and staffs were in operation. Congress provided the $19,000 appropriation for a skeleton staff and for expenses of national advisory committee operations, plus nominal expenses of state committees which are now on a standby basis. Because it now appears that several hundred physicians will have to be called before next June 30 via the draft, additional funds will be requested when Congress convenes in 1959. The National Advisory Committee has the responsibility of advising Selective Service on deferment policies for physicians in residencies, teaching positions, essential laboratory and clinical research and re persons deemed necessary to protect civilian health at a time when draft calls are being made. The state and territorial committees assist the national committee when their services are required.

OFFICE OF THE ATTENDING PHYSICIAN OF CONGRESS

(This Year: $13,145–Last Year: $12,145)

Since 1928, the Office of the Attending Physician of Congress has provided outpatient care for members of the House and Senate and their staffs. By an act of that year, the office has been filled by a medical officer of the United States Navy. Sole occupant of the post has been Rear Admiral George W. Calver (M. C.), U. S. N. Funds voted by Congress are for medical supplies and equipment and contingent expenses. Salaries of Dr. Calver, his assisting physicians and enlisted corpsmen are paid from Navy funds.

TABLE 2.—*Payments to Individuals Because of Disability Through Programs in Which the U. S. Government Participates (fiscal year ending June 30, 1959)*

(Small groups of federal retirees' plans not listed; administrative cost of program omitted)

Programs	Estimated Beneficiaries	Approx. Payments
Veterans Benefits		
A. Service-Connected Disability..........	2,445,000[a]	$2,013,000,000[a]
B. Non-Service-Connected Disabilities....	1,332,000[b]	1,135,000,000[b]
Military Retirement Permanent & Temporary Disability....................	82,600	221,840,000
Federal Employees Compensation (Payments)	136,500	24,835,000
(These programs fully financed by U. S.)		
Public Assistance		
A. Aid to Needy Permanently & Totally Disabled......................	336,000	260,200,000[c]
B. Dependent Children Aid (incapacitated father segment)......	722,000[d]	235,000,000[d]
C. Aid to the Blind.........................	108,800	90,400,000[e]
Disability Annuity Payments to Civil Service Retirees.....................	90,000[f]	127,000,000
(Public Assistance financed 55% U. S. & 45% states; Civil Service financed 50% U. S. & 50% employees.)		
Social Security—OASI Disability		
A. Disability Over Age 50................	262,000[g]	333,000,000
B. Childhood Disability Benefits[h]........	52,000[h]	24,000,000
C. Dependents of Disabled Workers[i]....	80,000[i]	50,000,000
(These programs financed by OASI Payroll Tax)		
Railroad Retirement Disability		
A. Permanent Disability for Regular Job	30,000	42,000,000
B. Permanent Disability for All Employment......................	71,000	88,000,000
C. Temporary Disability..................	150,000	50,000,000
(These programs financed 50% employers—50% employees.)		
Total......................................	5,897,900[j]	$4,694,275,000

[a] 388,000 dependents in this total; program decreasing as beneficiaries die.

[b] 511,000 dependents in this total; program is increasing rapidly.

[c] $143.9 million of this total is provided from U. S. funds. Additional program administrative cost is about $29.8 million (11.5%); U. S. *share is $14.9 million.*

[d] Provided to 167,000 families. $142.8 million of benefits is federal. Additional administrative cost is $22.8 million (9.7%); U. S. share is $11.4 million.

[e] U. S. contribution to program is $45.4 million. Additional administrative cost is $6.6 million (7.3%); U. S. share is $3.3 million.

[f] Number of persons in this program increased by 11,400 over last year.

[g] 262,000 beneficiaries are estimated at mid-year; by July 1, 1959 estimate is 330,000.

[h] Eligibility based on disability incurred before age 18; the 52,000 beneficiaries listed is at mid-year; by July 1, 1959 total will reach 73,000.

[i] Does not include any childhood disability beneficiaries entitled to benefits as dependents of disabled workers; the 80,000 beneficiaries listed is at mid-year; by July 1, 1959 total will reach 134,000.

[j] No adjustment made for payments to one individual through more than one program.

MEDICAL EDUCATION IN THE UNITED STATES AND CANADA

Fifty-Eighth Annual Report on Medical Education in the United States and Canada by the Council on Medical Education and Hospitals of the American Medical Association

ACKNOWLEDGMENT

The material presented in the following pages constitutes the 58th Annual Report on Medical Education in the United States and Canada, compiled by the Council on Medical Education and Hospitals of the American Medical Association. This report is concerned specifically with basic medical education, certain facets of graduate education beyond medical school, postgraduate medical education, and education and training in areas allied to medicine which have requested Council cooperation and participation. Detailed information regarding postgraduate medical education is presented annually in a separate issue of The Journal (Aug. 16, 1958). Graduate medical education including internships, residencies, fellowships, and certain pertinent data regarding the specialty boards is revised annually and has been published in the Oct. 4, 1958, issue of The Journal.

Table 1.—*New Four-Year Medical Schools Developed in the United States and Canada During the 15-Year Period 1943-1958*

Name of Institution	Originally Founded	Four-Year Program Instituted	First Graduates of Four-Year Program
Medical College of Alabama*	1859	1943	1946
University of California at Los Angeles	1951	1951	1955
University of Miami	1952	1952	1956
University of Florida	1956	1957	1961
University of Mississippi*	1903	1955	1957

University of Kentucky	Currently being organized		1961(?)
West Virginia University*	1902	Four-year program under consideration	
University of Saskatchewan*	1926	1955	1957
University of Ottawa	1945	1947	1951
University of British Columbia	1950	1950	1954

---

* Former two-year school of basic medical science.

The data presented cover the academic year 1957-1958 and have been derived from official sources in all instances. The basic questionnaire on which medical schools submitted their annual data for this report was prepared jointly by the Council on Medical Education and Hospitals of the American Medical Association and the Association of American Medical Colleges. Presentation of the following information has been made possible through the cooperation of medical school and university officials, representatives of government agencies, and the officials of the technical areas allied to medicine which are included.

The Council on Medical Education and Hospitals desires to express appreciation on behalf of the American Medical Association to those individuals and organizations who have cooperated in furnishing the information on which this current report is based.

FIFTEEN YEARS OF GROWTH

As one reviews the passing scene and notes the dates of establishment of medical schools, the past 15 years have witnessed remarkable developments. During this period 13 additional four-year programs have been activated in the United States and three in Canada. Two other schools (Kentucky and West Virginia) are in development but have not yet implemented their new programs. Eight of these currently activated four year schools represent entirely new institutions, and all but three of them (Florida, Albert Einstein, and Seton Hall) have already been adding physicians to the ranks of the profession through graduation of one to several classes of students. The other five institutions include those which have augmented their programs during this period from former two year schools of basic medical science to four-year degree-granting schools, all of which have graduated classes.

The University of Kentucky is currently engaged in the planning and development of its four-year school but has not yet activated its teaching program. West Virginia University School of Medicine is completing its new facilities and the faculty organization involved in converting from a two-year school of basic medical science to a four-year program.

In Canada, during this period, there have been two entirely new four-year medical schools and one institution which has converted its program from two years of basic medical science to a four-year curriculum.

Table 1 lists the institutions to which reference has been made, giving the original dates of their organization and also the dates when some schools starting as two-year institutions initiated four-year programs. The accompanying photographic reproductions portray these interesting and impressive facilities which have been developed during the 15-year period. In many instances the photographs give only a partial indication of the teaching, research, and clinical facilities utilized. In presenting the photographs of these four-year institutions developed during the 15-year period, it should also be indicated that practically all of the medical schools in the United States and Canada have benefited from additions to their physical facilities during this period and that a complete photographic story of such developments would fill many additional pages.

PROGRESS AND EXPERIMENTATION IN MEDICAL EDUCATION

MAJOR DEVELOPMENTS OF INTEREST

Forty-nine of the 85 operating medical schools in the United States and 7 of the 12 Canadian schools reported major new developments during the 1957-1958 period. These included changes in administrative organization (19 United States and 2 Canadian schools), changes in methods of student selection (9 United States schools), curriculum planning and activation of modified programs (26 United States and 5 Canadian schools), and significantly augmented financial resources (37 United States and 5 Canadian schools). Augmented financial resources covered funds for construction (20 United States and 1 Canadian school), student loans and scholarships (8 United States schools), salary adjustments, maintenance, equipment, research, and basic endowment.

It is significant that during recent years the areas in which most active major changes continue to occur are in matters of curriculum analysis and modification and in the financing of the many costly facets of medical education.

HISTORICAL NOTE ON THE CURRICULUM

In connection with curriculum studies and readjustments it is of interest to recall a historical note. On April 4, 1909, the Council on Medical Education reviewed a schedule of 10 subjects with the number of hours assigned and voted to recommend this 4,100-hour program as a "working schedule for the medical curriculum." In its minutes of that date the Council specifically stated that: "It was the general opinion of those present that this schedule should not be made a hard and fast requirement to which all colleges should comply, and that a strict uniformity of curricula among all colleges was undesirable." The schedule which had been outlined represented the combined opinion of over 100 leading medical educators who had been consulted before it was finally presented.

At their meeting the next day, April 5, 1909, the Council members reviewed their actions of the previous day. Fear was expressed by certain members that some of the state examining boards would adopt the standard curriculum set forth by the Council as a guide and make it obligatory on medical colleges if their graduates were to be qualified for examination. To counteract any such possibility the following resolution was adopted:

> Whereas, the object of the Council on Medical Education in appointing a Committee on Medical Curriculum was entirely educational and suggestive and,
>
> Whereas, the impression prevails among medical teachers and members of state boards that the Council is framing a curriculum for the purpose of having it serve as a standard to which medical schools must conform or be condemned by the state authorities as not in good standing, therefore be it
>
> Resolved, that every publication of a curriculum that hereafter may be made by the Council, its members, or its officers as such, shall state explicitly that the Council does not consider it in the interest of true progress in education that any standard curriculum whatever shall be uniformly adopted by all medical colleges.

DUKE UNIVERSITY INITIATES NEW PROGRAM

Among the developments of interest to medical education is the recent announcement of plans for a major educational program at Duke University, designed to produce physicians who are also skilled medical research scientists. As presented, the program is planned with the objective of training medical students and hospital resident physicians in the methodology and utilization of research tools and techniques. It is reported that the financial support for the first three years of operation will come from grants totaling over three quarters of a million dollars. Of this sum, approximately $500,000 will be utilized in the provision of quarters and equipment with the balance allocated for salaries and maintenance. The program will be housed in a new four-story addition to the Bell Medical Research Building at the Duke Medical Center. Construction was initiated during the summer of 1958, and it is planned to admit the first class of research students in July, 1959. The faculty will include six full-time teacher-investigators who will become members of the medical center staff. As currently envisioned, the program will be geared to train about 20 students, who will integrate the research training with their regular four-year medical school curriculum. Included also will be house staff physicians, a small number of Ph.D. candidates in the basic medical science departments and in nonmedical sciences. Student selection will be based largely on "evidence of a research bent of an inquiring, critical and original mind," and Duke students will be given priority consideration. The announcement indicated that the individuals composing the planning committee for this program include Dr. Eugene A. Stead Jr., Chairman, Department of Medicine; Norman F. Conant, Ph.D., Professor of Mycology; Dr. David T. Smith, Chairman, Department of Microbiology; and Dr. Joseph E. Markee, Ph.D., Chairman, Department of Anatomy.

RESUME OF FIRST YEAR OF JOINT STUDY OF THE UNIVERSITY OF BUFFALO SCHOOLS OF MEDICINE AND EDUCATION

The University of Buffalo School of Medicine has completed the first phase of a joint study with the School of Education to determine whether the instructional program in a medical school might be strengthened by the development among medical teachers of greater familiarity with educational principles and techniques. The first year of the investigation was devoted to an examination of current medical teaching practices by professionals

in education under the guidance of medical faculty members. During the next two years an intensive series of seminars and workshops were conducted jointly by the educational specialists and their opposite numbers in medicine for a small group of medical teachers who gave nearly half time for a full academic year to these studies. The topics which occupied them included the psychodynamics of the learning process and the influence which teaching exerts upon it; the nature of the medical student population and the influence of personal and environmental factors in the student body and faculty upon learning; the historical and philosophical background of higher education as it relates to medical education; and the materials and methods of instruction in a medical school and evaluation of student progress.

The project coordinator has reported that the thirteen medical teachers, representing the University of Buffalo and six other medical schools, who have now taken part in the program, are agreed that professionals in education can make an important contribution to education in medicine. An independent evaluation of the effect of the program upon participants confirmed the impression that both their attitudes and practices had been modified by the experience. The data accumulated during two years of seminars made it possible to identify those items in education which had the greatest impact upon the participating teachers. This information is now being used in the construction of a second phase in this joint project which will have as its objective the provision of a more realistic opportunity for medical teachers to engage in a concentrated period of study of educational principles and techniques in a medical context. The first of a series of two-week institutes on medical teaching was held in June under the joint sponsorship of the University and the Association of American Medical Colleges. It was attended by 25 representatives of 20 medical schools in the United States and Canada. It will be repeated once or twice in the 1958-1959 academic year and at intervals thereafter. In addition to the institutes which provide an opportunity for teachers in other medical schools to share this experience, a continuing series of seminars will be held for the Buffalo faculty.

This program is supported by the Commonwealth Fund.

UNIVERSITY OF WASHINGTON FACULTY TEACHING CONFERENCE

In September, 1957, the University of Washington medical faculty held a two-day conference on teaching in the clinical years. The entire faculty, basic science and clinical department members included, heard reports from some of their own colleagues who had visited outstanding teaching programs at other medical schools. The pros and cons of these programs and the possibility of utilizing certain of their advantageous aspects in whole or in part were thoroughly discussed. This conference was part of a study of patient care and teaching made possible by a grant from the Commonwealth Fund. The fourth of these annual conferences to be held by this faculty was scheduled for September, 1958, and was intended to focus attention on teaching of basic sciences during the clinical years.

REVIEW OF 30-YEAR EXPERIMENT WITH PRECEPTORSHIPS AT THE UNIVERSITY OF WISCONSIN

It is desirable on occasion for an institution to evaluate carefully the program innovations and curriculum modifications which have been made with specific objectives toward improvement of its medical education potentialities. The University of Wisconsin has reported its 30-Year Experiment in Medical Education through the medium of the Wisconsin Preceptor Program. As reported by Bowers and Parkin,[1] the students are enthusiastic over the program and apparently look forward to it as one of the high points of their medical school career. The students who spend 12 weeks out of the 48-week senior year in this program express the belief that this allocation of time for the preceptorship should not be reduced. Those students who have completed the experience indicate that its greatest benefit was the opportunity to see the acute disease problems which they do not encounter frequently at the University Hospital. They also find that their patient relationships are more intimate, penetrating, and more satisfactory as they make the initial contact with them rather than after the various preliminary admitting procedures involved with the patients at the teaching hospital. They have more opportunity to see the patient's family and to understand the total problem as well as to learn how to more effectively talk with patients. The experience with a preceptor sometimes helps to determine the field of medicine that the student decides he does not wish to enter as well as suggesting a possible major field of interest.

Bowers and Parkin indicate a few of the debits that have accompanied the plan. For instance, some students conceive of the preceptorship as an opportunity to prepare for internship. In some situations students see too many patients during the day and develop a tendency to utilize short cuts in their evaluations of individual patient problems. In other instances the student may be allowed to be too much on his own. Some students find they work harder during the preceptorship than during any other phase of their medical education and that there is inadequate opportunity for follow-up study.

Page and Anast,[2] in summarizing an alumni evaluation of this 30-year program, found that those who looked back on their participation in it as part of medical education were generally enthusiastic. It was considered to afford a close teacher-student relationship that had been of genuine value. The study could present no evidence that this preceptor program had acted to encourage graduates to enter the field of general practice or to settle in rural areas. On the contrary, it was of interest to note that the study revealed evidence that graduates of Wisconsin enter specialty practice with as great or greater frequency than the alumni of comparable medical schools which have not included preceptorships in their programs.

WESTERN RESERVE REPORTS ON FIRST EVALUATION STUDIES

It is now 12 years since the faculty of the School of Medicine at Western Reserve University initiated the planning of the program of medical education which was activated in 1952. The new program at Western Reserve was an outgrowth of growing dissatisfaction with existing programs and the conviction that the education of physicians could be improved in a number of ways. As the program developed the faculty has been confronted by questions as to whether it is possible to evaluate it effectively in a way as to provide meaningful results. There has been continuing critical study of the program by a subcommittee on evaluation which was established in 1953 and which has endeavored to develop a broad concept for research in medical education. Dingle and associates[3] have recently outlined the approach to the problem of evaluation and indicated the fields in which their studies are being done. They have suggested the need for suitable evaluation of any program in medical education, and their experience to date has emphasized some of the difficulties inherent in any such effort. Their studies have shown that research in medical education appears to be as greatly needed as it is in other fields of endeavor. In fact, it is suggested that consideration be given to establishing, at the school, an adequately staffed division of education research with the primary concern of (1) evaluation of the effectiveness of the program in relation to objectives and in relation to standards of contemporary medical education; (2) research in student development; (3) research in teaching methods; (4) research in testing methods; and (5) training of investigators in educational research.

The first report of the Western Reserve studies has been presented by Horowitz, Brozgal, and Eaton[4] and deals with observations of first-year students in preceptoral groups. This report presented observations of the reactions of first-year medical students in preceptoral groups in a clinical science program and, to a limited degree, described the behavior of their preceptors. It is recognized that full evaluation of the effectiveness of a program such as that being conducted at Western Reserve University will not be possible until a considerably longer period of "follow-through" has elapsed. This first report, however, presents some important challenging observations which merit careful study on the part of those concerned with ways and means of improving medical education. While the study reports only part of the over-all program, it records observations of positive value that may well be utilized in part by other institutions pursuing experimental reorientation of the early phases of the medical curriculum.

INTRODUCTORY STUDIES IN THE SOCIOLOGY OF MEDICAL EDUCATION

Another valuable contribution in the field of medical education was the publication of the Introductory Studies in the Sociology of Medical Education. In this volume, Merton, Reader, and Kendall,[5] present a collection of papers constituting the first set of reports on continuing studies in the sociology of medical education which were begun several years ago by the Bureau of Applied Social Research of Columbia University. This study was conducted in collaboration with the students and faculties of the Schools of Medicine of Cornell University, University of Pennsylvania, and Western Reserve University. These introductory presentations are apparently intended to be part of a periodic series of reports of special studies in the sociology of medical education which will extend over a number of years before any final comprehensive synthesis will be attempted. Eventually the studies will include the sociological evaluation of graduate medical education which is discussed elsewhere in this current education number of THE JOURNAL.

In its initial section this first report deals with a thought-provoking section on preliminaries to a sociology of medical education, and a resume of the Cornell Comprehensive Care and Teaching Program. The second section is concerned with career decisions such as the decision to study medicine, some comparisons of medical and law school entrants, and tendencies toward specialization in medical training. The third section discusses the processes of attitudinal learning and the final portion of the report presents changes in the Cornell Care and Teaching Program and the range of patient contacts in it. Again, this report brings together in better focus certain aspects of an experimental program in medical education that has been underway for a number of years, presenting data of value to other institutions considering curriculum realignment.

PITTSBURGH OUTLINES PLAN OF EXPERIMENTAL PROGRAM

Moses, Gregg, and Danowski[6] have presented an outline of an experimental curriculum of medical education for modern medicine which is being developed at the University of Pittsburgh. It is designed to permit a small number of students greater flexibility in their college and medical educational experience. The program as suggested would permit those students deeply interested in a scientific career in a medical field to pursue a course more appropriately designed to such an objective. Likewise, it would make it possible for the students primarily interested in becoming family physicians or clinical specialists to participate in educational experiences designed toward such ends. Both scientific and humanistic aspects of the program would be strengthened to permit potential scientists and clinical specialists to initiate the specialized phases of their education at an earlier date. Furthermore, it is believed the curriculum of students electing the clinical practice of medicine will provide a more effective educational experience than the current all-purpose, 9-year course.

At the beginning it is planned to select a small group of students on the basis of their early collegiate experience and permit them to take some of their courses along with regular medical students. Subsequently, the curriculum of these students will be modified in accord with their interests and abilities so as to provide both a sound general education and a more effective basis for their ultimate career objective. This would be accomplished through the judicious utilization of summer periods and reorienting of students through the current departmental structure to provide the most effective individual objective. The individualization required by such a program will necessitate careful and exacting counsel and guidance and will be interesting to observe in action.

ANNUAL TEACHING INSTITUTE OF ASSOCIATION OF AMERICAN MEDICAL COLLEGES

The 1957 Teaching Institute of the Association of American Medical Colleges, held in Atlantic City, Oct. 16-19, focused attention on the ecology of the medical student. This was the second successive institute which was primarily student-centered, the preceding one having dealt with the appraisal of applicants to medical schools. The major areas considered included (*a*) the various intramural forces affecting medical students; (*b*) the diversity of values and objectives in medical education; (*c*) noncurricular factors affecting medical students; (*d*) the development of professional attitudes and capacities; and (*e*) educational patterns for medicine. The 1957 Teaching Institute stimulated further interesting and critical self-appraisal and intercommunication in regard to the student in the process of medical education.

The 1958 Institute conducted at Swampscott, Mass., Oct. 7-11, was the first of the institutes dealing with clinical teaching. Many individuals in medical education have been awaiting with interest and anticipation the first of the clinical teaching institutes. This institute dealt with such areas as (*a*) objectives of clinical teaching and (*b*) the variation of emphasis in objectives such as (1) the case for emphasis on the practical and encyclopedic, (2) the case for emphasis on social forces and environment, (3) the case for emphasis on scientific method, (4) "The Science, the Art and the Heart; A Synthesis of Objectives in Clinical Teaching"; and (5) the extramural forces influencing medical education from the point of view of the philosopher, the economist, and the behavioral scientist. It also dealt with the setting of clinical teaching including medical service in the teaching hospital, the relationships of a university to a teaching hospital, and hospitals and clinical teaching. The third general topic centered on the student, the patient, and the teacher and covered considerations of the clinical teacher and scholarship as the heart of the educational process. It also considered student participation in the teaching process, patient care as a social process, and a presentation of clinical teaching in the European system of medical education.

There is no question but that the previous institutes sponsored by the Association of American Medical Colleges have led to markedly enhanced intercommunication between medical faculties throughout the nation as well as within the schools themselves. The follow-through from the 1958 institute promises to continue in the further stimulation of this desirable trend.

FOCUS ON FUTURE NEEDS IN MEDICAL EDUCATION

CHALLENGES TO MEDICAL EDUCATION

At the 54th Congress on Medical Education and Licensure held in Chicago, Feb. 9-11, 1958, attention was focused on the challenges and future needs in medical education. The reasoning behind and the purpose of this Congress was presented by Dr. Leland S. McKittrick,[7] Chairman of the Council on Medical Education and Hospitals, by posing the question: "Are those responsible for supplying medical needs to the people in this country aware of what these needs will be in the forseeable future, say in the next 15 to 20 years; and are proper and effective efforts being made to meet them?" Doctor McKittrick indicated the emphasis that had been placed on physician-population ratios and raised a second question as to whether the answer to this situation was as simple as the production of new physicians in proportion to the increase in population.

Addressing the Congress as President of the American Medical Association, Dr. David B. Allman[8] indicated that: "changes affecting every aspect of human life are occurring at an ever accelerating rate" and that "they have presented new problems and challenges to medicine and its allies as well as to other areas of activity." These changes have been reflected by "sincere concern in regard to the education, training, and development of the personnel needed to meet and solve effectively the problems with which they will be challenged."

Dr. Allman further commented:

> It is not surprising that, with the current widespread interest in health, this changing scene has been accompanied by representation from various sources of increased needs for medical and allied personnel. No one will deny that, as our population grows at a rate far beyond estimates of a few decades ago, as health consciousness continues to grow, and as new problems arise, there will be continuing need for increased numbers of well trained medical personnel. This will necessitate the facilities, finances and faculty essential to their education and training.

He reflected the concern of other thoughtful individuals:

> In the current complex setting it is not possible to plan for medical personnel needs in simple arithmetical physician-population ratios as might have been the case in earlier years. One fact, clearly certain, is that efforts to compare unqualified statistics for physician-population ratios in recent years with those early in the century is not only meaningless, but actually misleading.

Dr. Allman pointed out, as has the Council on Medical Education and Hospitals on previous occasions,[9] that the question as to "How many doctors are enough?" has become increasingly difficult to answer. Such a reply necessitates a detailed knowledge of trends in medicine and medical practice as well as efforts to forecast further population growth and shifts, continued social and economic readjustments, and the constantly increasing dimensions of scientific knowledge.

Because of its direct relation to the theme of this section of the 58th Annual Report on Medical Education in the United States and Canada, the final paragraphs of Dr. Allman's address are quoted in full.

> American medicine is deeply and sincerely interested in the future education and training of the nation's physicians. It has a right to be proud of the responsible role its Association, in cooperation with other organizations, has played in the development of the high standards of medical education and medical care which exist in the United States today. If we are to maintain high standards and play our role of responsibility in the fulfillment of the needs that lie ahead, American medicine must objectively look at current trends in population, society, economy, and at the vastly changing dimensions of knowledge within its own field in an effort to clearly define some of the questions to which answers must be found.
>
> Today danger confronts our civilization, but opportunities greater than any existing before are also present. Opportunity can be lost if responsibility is side-stepped. One may not be responsible for something that happens when his eyes are shut; but even so, he may eventually be called to account for having his eyes closed at the very moment when they should have been wide open and alert.
>
> We in American medicine must carry our responsibility in objectively and constructively playing our role to assist in defining as clearly as possible the questions concerning future needs for the education and training of physicians. "Responsibility," it is said, "walks hand-in-hand with capacity and power," and the manner in which it is utilized can be the determinant of any individual or group's contribution to his fellow men.
>
> Norman Cousins has recently stated: "What the Nation needs today even more than scientists is men of wisdom and vision. It urgently needs men with the clear and full view, men who understand what is happening in the world and are not continually being taken by surprise by living history and the effects of recognizable causes."

The subsequent presentations of Kirk,[10] Parsons,[11] Kestnbaum,[12] and Hussey,[13] clearly and succinctly portrayed to the Congress the current trends and challenges of the changing characteristics of our population, society, economy, and the changing dimensions of medical knowledge. Each of these four areas was carefully considered by workshop groups who subsequently reported their conclusions to the Congress. These basic challenging background presentations and the workshop resumes appeared in the May 3, 1958, issue of The Journal and merit careful study on the part of all individuals interested in any or all aspects of this matter of projection of estimated needs in the field of medical education.

The Congress also focused attention on some of the problems in specialty training resulting from the changing status of the patient. The background for this study was portrayed by Dr. Ward Darley,[14] Executive Director of the Association of American Medical Colleges, who pointed up the problems in undergraduate medical education associated with the changing status of the patient as well as some of the other specific challenges confronting this field in the area of financing and faculty policies. The specific challenge on problems in specialty training created by the changing status of patients was presented by Dr. T. Stewart Hamilton.[15] Zintel,[16] Williams,[17] Lawson,[18] and Barnes[19] outlined the manner in which surgery, medicine, pediatrics, and obstetrics and gynecology may meet some of these problems in graduate medical education. Burgess and Leonard,[20] presented the manner in which the community hospital may play an important and significant role in graduate medical education today.

The 55th Congress on Medical Education and Licensure scheduled for Feb. 8-10, 1959, will focus attention on the areas of specialism and research. The role of research in relation to medical education has become increasingly important over the years and now presents many facets that merit serious study as plans are developed for new medical schools and for progressive realignment of activities in those currently in existence. How can medical education and medical research be further developed to their best mutual advantage? Where is mutual advantage lost in the more direct interests of either education or research? How can research best contribute to medical education, and how does medical education strengthen research activities? These and many other questions of deep interest and concern to medical educators, those engaged in higher education in areas other than medicine but having potential contributions to it, hospital administrators, and those concerned with current specialty education and training should make this program one of very real interest. Some of the current trends in specialization have likewise given cause for careful scrutiny. The trend towards increasing inflexibility in some specialty areas, the means of evaluation of residency and other forms of specialty training, the emphasis on time as a measure of adequacy of training, the problems involved in evaluation of quality and content of education and training in the specialties, the specialty boards, the Advisory Board for Medical Specialties, and the residency review and conference committees will all enter into the considerations to be given to this area of medical education.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS SUPPORTS DEVELOPMENT OF ADDITIONAL FACILITIES FOR BASIC MEDICAL EDUCATION

The 1956-1957 Annual Report on Medical Education in the United States and Canada[21] included a statement on the future need for physicians which had been prepared by the Association of American Medical Colleges. The Council on Medical Education and Hospitals[22] has previously indicated the existence of the challenges in this field presented by the increasing population, rapid accumulation of scientific knowledge applicable to medicine, and the changing social and economic facets of the American scene. The Council on Medical Education and Hospitals as is indicated in the following statement supports its own previous comments and those of the Association of American Medical Colleges as to the desirability of developing additional facilities for medical education.

Through the medium of its various activities and particularly in its Annual Report on Medical Education in the United States and Canada, the Council on Medical Education and Hospitals of the American Medical Association has endeavored to present and interpret the changing scene in medical education to the profession. With the support of the medical profession and in cooperation with the Association of American Medical Colleges, the American College of Surgeons, the American College of Physicians, the various specialty boards, the Joint Commission on Accreditation of Hospitals, the American Hospital Association, and other organizations, constant and sincere efforts have been made to assist in the advancement of medical education in keeping with the knowledge, trends, and needs of the period.

In recent years the position of the American Medical Association in regard to present and future needs in medical education has frequently been misinterpreted by many individuals and by some organizations through the misuse of statistical data. Statistical information has at times been taken out of context and interpreted to the effect that the official position of the American Medical Association is that there is no need for increased numbers of physicians. No such official position has ever been enunciated. American medicine, as was indicated earlier in this report in reference to Dr. Allman's comments at the 54th Congress on Medical Education and Licensure, fully recognizes the needs being brought about by the increasing population, social and economic trends, and the changing dimensions of medical knowledge and its application. The primary concern of American medicine is that these needs be carefully analyzed and that they be met as a result of sound developments based on the best possible knowledge.

The Council on Medical Education and Hospitals recognizes that the physician-population ratios, on which most current projections of medical personnel have been made, have remained relatively constant for a number of years. It is difficult, however, in the rapidly changing modern scene, to determine whether this relative ratio of physicians per unit of population might be reduced or should be augmented to meet the medical care, teaching, and research challenges of the future. On the other hand, the increasing population together with the various other facets of the shifting pattern obviously indicate the need for constantly increasing the number of physicians. This necessitates consideration on the part of existing medical schools as to possible augmentation of the number of students admitted as well as the development of new facilities. Furthermore, the Council believes it is a logical function and responsibility of American medicine to encourage institutions of higher education where medical education has not been undertaken in the past to give serious consideration to the development of opportunities in this field if all other factors make it appear desirable to do so. The Council on Medical Education and Hospitals sincerely believes it is a responsibility of the American Medical Association to take effective leadership in presenting these increased needs as objectively as possible.

The Council on Medical Education and Hospitals and the Association of American Medical Colleges, independently and through the Liaison Committee on Medical Education, are on record in encouraging the consideration and creation of both four-year programs of medical education and of two-year programs of basic medical science, where institutions of higher education offer the setting which would make such developments mutually advantageous and desirable.

FUNCTIONS AND STRUCTURE OF A MODERN SCHOOL OF BASIC MEDICAL SCIENCES

Because of interest in the contribution to medical education that might be made through the development of thoroughly excellent, additional two-year Basic Medical Science programs, the Council on Medical Education and Hospitals of the American Medical Association, and the Executive Council of the Association of American Medical Colleges have collaborated in preparation of a document or guide outlining their essential features. This statement entitled "Functions and Structure of a Modern School of Basic Medical Sciences" has been approved by the two Councils, and the Liaison Committee on Medical Education subsequently endorsed it.

The general format of this document follows that of the collaborative statement on "Functions and Structure of a Modern Medical School" which was published recently to replace the former "Essentials of an Acceptable Medical School." After presentation to and approval by the House of Delegates of the American Medical Association and by the Association of American Medical Colleges at their next meetings (A.A.M.C., October, 1958; A.M.A., December, 1958), the statement will be published for distribution as early as possible.

REPORTS OF CURRENT INTEREST TO MEDICAL EDUCATION

COOPERATION IN MEDICAL EDUCATION

The 1957-1958 Report of the Council on Medical Education and Hospitals to the House of Delegates of the American Medical Association includes the following comments concerning cooperation in Medical Education.

> In 1942, after consultation with, and approval by the Board of Trustees, the Council developed an official working relationship with the Association of American Medical Colleges, the official organization of the medical schools, through the establishment of a Liaison Committee on Medical Education. Through this arrangement, it has been possible to share responsibilities, problems, challenges, and viewpoints in the many areas where the Council and the Association of American Medical Colleges have mutual concern and similar objectives.
>
> The effectiveness and productiveness of this liaison has resulted in the development of somewhat similar working relationships with appropriate organizations in other fields of concern to the Council. The responsibilities and objectives in graduate medical education and specialty training clearly overlap with those of the Advisory Board for Medical Specialties and with the individual specialty boards. This field of mutual endeavor now has formal expression through a Liaison Committee with the Advisory Board and through the various residency review committees. Similarly, the Internship Review Committee was formed to give other organizations that have a legitimate stake in the internship (e. g., the American Academy of General Practice, the Association of American Medical Colleges, American Hospital Association, and the Federation of State Medical Boards) an opportunity to share viewpoints and efforts in this part of the Council's activities.
>
> There are many other effective working partnerships now in existence and, at the present time, with the concurrence of the Board of Trustees, planning is underway to establish a liaison committee consisting of representative of the Board of Trustees, the Council on Medical Education and Hospitals, University Presidents, and the Association of American Medical Colleges. It is believed that this holds great promise for future better understanding and relationships on the part of organized medicine and its agent in medical education, the Council on Medical Education and Hospitals, with universities, who are ultimately responsible for the conduct of medical schools, and the Association of American Medical Colleges, which can be considered as the universities' agent in medical education.
>
> The Council is of the sincere belief, based now on many years of direct experience, that this approach of cooperation and collaboration has worked to the distinct benefit of the Council's major objective as charged by the House of Delegates many years ago to "make suggestions as to the means and methods by which the American Medical Association may best influence favorably medical education' and to 'act as the agent of the American Medical Association (under instructions from the House of Delegates) in its efforts to elevate medical education."

COLLABORATION WITH THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES

In cooperation with the Association of American Medical Colleges, the Council on Medical Education and Hospitals has prepared a number of important basic documents dealing with matters of concern in medical education. The former "Essentials of an Acceptable Medical School" prepared by the Council and authorized for publication by the House of Delegates of the American Medical Association has been replaced by "Functions and Structure of a Modern Medical School," representing the combined efforts of both groups. It was approved by the House of Delegates of the American Medical Association in June, 1957, by the Association of American Medical Colleges in October, 1957, and published in late fall of 1957.

On June 1, 1958, the Council on Medical Education and Hospitals of the American Medical Association and the Executive Council of the Association of American Medical Colleges authorized and published a statement on "The Present and Future Status of Foreign Medical School Credentials in the United States." This statement includes informative data on the Educational Council for Foreign Medical Graduates, the present and future status of the list of foreign medical schools, the present and future status of graduates of foreign medical schools seeking internship and residency training in the United States under the Exchange-Visitor Program, and those entering the United States on permanent (immigration) visas. It also includes information on the status of American citizens studying medicine outside the United States and Canada, the policy of the American Hospital Association concerning graduates of foreign medical schools, and the policy of the National Intern Matching Program in regard to such individuals.

For many years the Council on Medical Education and Hospitals has sent out an annual questionnaire to each medical school in the United States and Canada for information on which the data in the education number of The Journal have been based. In order to overcome needless duplications and to obtain identical and more comprehensive information for the Council on Medical Education and Hospitals and for the Association of American Medical Colleges, this year the annual questionnaire has been developed as a collaborative effort.

In these and many other areas there has been excellent liaison between the American Medical Association and the Association of American Medical Colleges. The "top level" liaison mechanism which will include representation from University Presidents and the Association of American Medical Colleges, on the one hand, and the Board of Trustees of the American Medical Association and the Council on Medical Education and Hospitals, on the other hand, holds great promise in the future for the discussion of problems of mutual concern. It should result in minimizing areas of difficulty and misunderstanding such as have been precipitated during recent years by the changing character of medical practice, the changing status of the patient, and the changing character of the faculties of medical schools.

FINANCING MEDICAL EDUCATION

THE CARROLL STUDIES ON COSTS OF MEDICAL EDUCATION

There is a continuing interest in relating medical school operating expenditures to the functions the expenditures support. Mr. A. J. Carroll, Business Officer of the State University of New York, Upstate Medical Center, on request, submitted the following statement pertinent to this important matter.

Medical education today faces serious financial problems. However, we can be sure that if they are reported efficiently they will get wide attention and be dealt with efficiently. For the most part, failures and delays in coping with these problems have been the result of inadequate financial reports.

The people of this country want, and will always demand, the best in medical care. They have established standards of excellence for health care, and by so doing they have set the standards for medical research and for their hospitals, doctors, and medical colleges.

For all branches of medicine the fountainhead of quality is medical education; anything that affects medical education will also affect medical research, medical practice, and medical care. Consequently, the problems of medical education are important not only to educators but to those in the health professions and to the general public.

To attain and maintain high standards a medical college needs money. An adequate supply of money will not guarantee a high level of operation by a medical college, but if there is a lack of sufficient funds over an extended period, substandard operations and results will be inevitable. Despite the large amounts of money which have been provided to the medical colleges, it can be stated categorically that their financial support has been inadequate; that the over-all quality of medical education has been adversely affected by this inadequacy; that the standards of medical care, as set by the American public, have not been fully met; and, that this failure to meet standards will grow gradually worse until more adequate support is provided.

While medical education holds the key which can give or deny the best of medical care to the American public, less than 1% of the nation's bill for medical care is being spent for medical education. This is seed money, the smallest but most productive portion of the total medical care bill. Buying anything but the best in this area would not only be uneconomical and unwise, it would endanger the health and security of our nation.

Importance of Financial Reports: We can be sure that the American public wants, and will pay for, the best in medical care, but we can be equally sure that they will insist on getting full value for their money. Therefore, it is essential that their concepts of full value be based on a clear understanding of the vital relationship between medical care and medical education. The amounts needed for medical education may appear small compared with the total costs of medical care but they loom large indeed when compared with the costs of other educational programs.

Educators, doctors, students, health personnel, legislators, government officials, university officials, and the general public—all are confused about medical education, what it costs, what it means to them, what they are paying for it, and what they should be paying.

They are confused because few medical colleges have reported costs and financial data that can be appropriately compared with those of other medical colleges, why its costs are more or less than those of other colleges, the actual cost of educating a doctor, the cost of each instructional, research, and service program, and by whom and to what extent each of these programs is supported.

Without this kind of financial information how can a medical college appraise the efficiency of its own administrative practices and policies? How can it prove that each dollar entrusted to it is being used efficiently, substantiate its proposals for improvements, and know to whom it most appropriately might look for additional support? How can it benefit most from the experiences of others? Without such information, those upon whom the colleges depend for financial and moral support will remain confused and will be seriously handicapped in their efforts to provide the colleges with sufficient operating funds.

Inadequacy of Medical College Financial Reports: The foregoing does not imply that medical colleges do not keep books or prepare financial reports. Every college reports its income and expenditures, but the reports have been misleading. Recent studies have shown that the basic reason for this is the complete lack of uniformity in medical college budgeting, accounting, and reporting policies, practices, and terminology. As a result, the "costs" reported by each college reflect entirely different combinations of university, medical center, and medical college activities and expenses. Such costs are not suitable for comparisons.

Income reports have been defective because medical college "income" has not been precisely defined. For example, some colleges report tuition receipts as medical college "income" even though they are deposited in the general funds of the university or state and cannot be used for the support of college programs. For colleges that follow this practice, tuition represents "earnings" but not "income." Colleges may report state budget appropriations or university general fund budget allocations as "income" while in reality only the portion of these appropriations that is spent benefits the colleges and is the equivalent of "income." Often the unspent balance remains in, or reverts to, the university or state general funds. If a medical college retains the unspent balance, the entire appropriation or allocation should be reported as "income." However, if these unspent amounts are reappropriated for the following year, they should not be reported again as "income." In response to questionnaires some medical colleges have reported the same money as income in two or more successive years. Where these illustrations apply, income may be overstated, possibly to the detriment of the college.

Financial support for the medical college which comes indirectly through the university, hospitals, special funds, or other agencies seldom is reflected in the "income" report. In such cases "income" and "sources of financial support" are not the same.

For these and other reasons medical college "income" reports have been indefinite and have had limited significance for comparative purposes. To provide appropriate comparisons, reports of the "sources and amounts of financial support for medical college programs" are necessary. Obviously, all such reports should be prepared in accordance with uniform practices, and the terminology should be defined precisely.

Most medical colleges report their "expenditures" as "costs," and cost reports, for the most part, have been budget reports—the amounts actually spent under the medical college budget. The trouble is that the "expenditures" of a college seldom represent the true "costs" of medical college operations —the actual values that are being sacrificed to support the medical college programs.

The university may contribute a variety of business, plant, library, and student services and expenses; hospitals, clinics, special funds, and other organizations may pay faculty salaries or contribute essential facilities and supplies for the support of activities or functions common to all medical colleges. Medical college "costs," to be useful and comparative, must include these values, even if they are not charged to the medical college budget. Suppose, on the other hand, that the "expenditures" of a medical college include support of activities and programs that normally would not be charged to a medical college. To produce comparative "costs" these expenses must be identified, set aside, and excluded from "medical college costs." In other words "medical college costs," to be appropriately compared, must reflect the total costs of an identical combination of medical college programs and activities—the programs and activities common to all medical colleges.

Despite the complicated programs, responsibilities, and relationships which make medical education unique in comparison with other university and government activities, there have been continuous attempts to fit medical colleges into the normal management patterns of colleges, universities, and states. Not enough thought and effort has been applied to the special problems of the medical colleges. To illustrate this, let the medical college administrators ask themselves, "What is our accounting accounting for?"

For years the medical colleges have been telling those responsible for approving and supporting their programs *how* they have spent their money—the salaries and expenses they have paid and the things that they have bought. This is useful information for day-to-day management purposes, but trustees, legislators, and many others draw dubious comfort from reports which place major emphasis on the colleges' success in spending hard-to-get funds. They would rather be told what they are getting for their money.

This calls for program accounting and reports to show the costs of undergraduate education, graduate education for advanced degrees, intern and resident training, continuation education, medical research, community health services, patient services, etc. These are the programs for which a medical college is primarily responsible. To tell what it has done, what it is doing, and what it plans to do, a college must report in terms of these programs; and such reports, to be meaningful, must be expressed in dollars, the language of business.

With program costs, figures are supported by related facts, the cost of educating a doctor can be reported, and the common but improper method of determining per-student costs by dividing total medical-college costs by the undergraduate enrollment can be discarded. With program costs a financial profit or loss figure can be determined for each college program. By carefully relating program costs and the sources and amounts of financial support, a medical college can tell the extent to which various persons, organizations, or segments of the general public are benefiting from its operations and so will know to whom it can justifiably look for additional financial support.

This is financial reporting for everyone because it tells everyone what he is getting for his money; it presents a comprehensive, nontechnical picture of medical education. Program accounting and reporting also will be used extensively for future planning, for budget justifications, and as a check on over-all operations. It is a once-a-year procedure and, therefore, inexpensive.

For these things alone, program accounting will be justified. It should be understood, however, that it cannot replace the customary, detailed object-of-expenditure type of accounting for day-to-day budgetary control.

In this country management generally has accepted the Whitehead philosophy that a fact in isolation is of little significance. So few persons would question the desirability and the need for comparing cost and financial data that a lengthy justification of efforts to produce comparative data is not necessary. The principal reasons are the following. 1. Through appropriate comparisons one college can benefit from the experience of others and avoid unnecessary experimenting. 2. Reliable comparative data will be essential for the planning of new medical colleges and the expansion, enlargement, and improvement of those now in existence. 3. Comparative information will make it easier for those responsible for medical education to evaluate the programs and financial needs of medical colleges. In the past the lack of such data has resulted in inaccurate evaluations and inadequate financial support. 4. Quantitative reports, comparisons, and analyses are more meaningful to the general public and will influence public opinion more than individual reports would. 5. Granting agencies and foundations need quantitative and comparative financial data to determine the relative needs of individual colleges, to serve as guides for policy making, and to help them make equitable distributions of available funds.

Cost comparisons are inevitable. If those directly responsible for medical education do not make them, others will do it for them. When others do it, the comparisons will usually be made on the basis of incomplete facts and figures and will be inappropriate, dangerous, and harmful.

At this point, one might well ask: What has been done to improve medical college financial reporting? Why hasn't budgeting, accounting, and reporting uniformity been established? Why aren't program costs in common use?

For several years the need for more meaningful financial reporting has been recognized at all levels of management. Financial studies have been made, and several of them have produced ideas which with proper support and application could have led to improved reporting and uniform financial practices. However, the necessary support and cooperation did not develop and the potential long range benefits of several good studies were lost.

The colleges have told about their complex programs and have explained how these programs are so intermingled that they cannot be separated, that it is impossible to distinguish the cost of educating a doctor, the cost of research conducted by the college, etc. That these explanations have been accepted year after year without serious challenge is a tribute to the faith of the American public in its doctors. However, medical education costs have become so high that new sources of support must be found. In seeking additional support, medical colleges are competing with other worthwhile proposals. To compete successfully, they must be able to describe their needs and their operations in terms of cost and in terms that will be understood and accepted by all concerned. Program costs will be essential.

Plans for Improved Financial Reports: The report of the recent State University of New York cost study[23] demonstrates rather conclusively that medical college fiscal operations can be analyzed in a manner that will produce appropriately comparable medical college costs. It provides detailed procedures and directions to help other medical colleges to study and analyze their own operations and compare them with the nineteen colleges covered by the report; it also describes a practicable, inexpensive system of program cost accounting and reporting. Another recent report[24] deals principally with a program analysis of medical education costs at Emory University. This report will help any medical college to understand and use program accounting more effectively. There is no serious conflict between either the principles or the methods of program cost analysis described in these two reports.

The Association of American Medical Colleges recognizes[25] "the inability to develop and report information that will permit the fiscal understanding of the manifold activities of our nation's teaching medical centers" . . . as "one of the major problems facing medical education." The Association has assumed a role of leadership to resolve this problem and it appears that it will have the enthusiastic support of all concerned.

During 1958 the Association has published the Emory University[24] and State University of New York[23] reports, and it has also obtained a grant from the W. K. Kellogg Foundation to finance a one-year "Study of Medical College Financing."

In brief, the major objectives of this study are (*a*) to develop methods to be used by all medical colleges for routine, periodic financial analyses and reports and to make a pilot study of six or eight colleges to test and prove the principles, definitions, checklists, analyses, methods, and procedures which eventually will be used for a nationwide financial study. (This will involve studying and standardizing basic fiscal policies, practices, and terms), (*b*) to develop a practicable and inexpensive system of program accounting and to help the colleges to place the plan in operation, and (*c*) to study and clarify related fiscal and management problems.

After the analysis, interpretation, and reporting of the pilot study findings, another objective will be to prepare a proposal including forms, procedures, staff, and budget that will permit the application of this study to all medical schools that are willing to be so studied.

The committee for the pilot study believes that a questionnaire type study will not suffice. Personal visits will be made by the study director to make sure that each item of information is correctly understood and reported and to check on the interpretation of questionnaire inquiries. The personal contacts also will be in line with the committee's recognition of an essential need for a continuing educational program to help medical college administrators to adopt and use uniform management methods and reports. The A.A.M.C. doubtless will assume leadership in such an educational endeavor. In this pilot study major emphasis will be placed on the long range, continuing benefits to come from the development of uniform accounting, budgeting, and financial terminology for the use of all colleges, and the development of procedures and plans for routine, periodic financial reporting by all medical colleges.

It is apparent that medical colleges have been the victims of over simplification, and as usual the oversimplified reports have been misleading. In the new study the axiom that an accounting system or report cannot be more simple than the complexities to be dealt with will not be overlooked.

A satisfactory financial report for a medical college cannot be simple. However, completely new accounting systems rarely will be needed. It will be necessary merely to establish standard terms and consider facts as well as figures so that differences can be recognized and adjusted for reporting purposes. The individuality of a college will not be lost or even threatened.

This study is well under way, and there is every evidence that within the foreseeable future those who are responsible for medical education and its financing will be consistently guided and fortified by complete, reliable financial and operating facts and figures. For the first time they will be able to prove the financial needs of medical education and establish new standards of management efficiency. The important role of medical education in the United States will be more fully appreciated, and more adequate financial support will be provided.

AMERICAN MEDICAL EDUCATION FOUNDATION

To acquaint readers with the activities of the American Medical Education Foundation the following report has been submitted by its executive director.

Almost eight years old, the American Medical Education Foundation continues to show concrete progress in its efforts to mobilize support for the schools from the medical community. Its total income since 1951 has now passed the 7 million dollar mark. During 1957 it received 44,155 contributions, an increase of almost 5,000 givers over the previous year, and it distributed $984,787 in grants to the medical schools from its 1957 collections during February, 1958.

This significant sum of money was raised through physician committees in state and county medical societies across the country. These committees have been developing steadily in each state and now have a degree of permanence and acceptance that outweighs the income each has secured because the active interest in, and sympathy for, the medical schools and their problems adopted by these committees are creating an opportunity for better communications between the profession and the schools.

TABLE 2.—*Physician Giving to Medical Schools in the United States Showing Restrictions on Use Money Made by Donor*

Restriction	Amount of Contributions
Unrestricted	$1,467,067.51
For teaching budget	48,852.55
For specific department	85,806.37
For building fund	895,946.91
For research	201,015.18
For scholarship and student aid	71,750.74
For library	8,810.08
For endowment	123,272.52
Others	115,018.54
Total	$3,020,600.43
American Medical Education Foundation	984,787.00
Totals	$4,005,387.43

During the past year the Foundation has continued to explore ways in which its efforts and those of the alumni arms of the schools could be coordinated. A meeting between the Foundation's board of directors and representative alumni directors was held in February at which time the possibilities and problems of such coordinations were discussed.

As a companion to these explorations, the Foundation continues to collect data from the schools on physicians giving directly to the schools. Until two years ago those reports were limited to unrestricted contributions. In 1956 and 1957 all physician giving was tabulated by the restriction placed on the gifts by the donor. In this way a truer picture of the financial support received by the schools from the medical profession was developed. Table 2 shows these totals by restriction.

This steadily increasing annual giving from the graduates of the medical schools reflects their growing awareness of the financial problems of medical education.

NATIONAL FUND FOR MEDICAL EDUCATION

The accompanying resume has been submitted by the staff of the National Fund for Medical Education to acquaint readers with the current activities of the Fund in support of medical education.

The National Fund for Medical Education in January awarded grants totaling $3,078,825 to the nation's 82 accredited medical schools. This was the largest annual award in the Fund's history and brought to $15,743,766 the total distributed by the Fund since its first grants were made in 1951.

Each four-year school received $15,000 plus $65 per undergraduate medical student. The four two-year medical schools of the basic medical sciences received $7,500 each, plus $65 per student.

In addition, in May, the Fund made grants totaling $99,608 to 14 medical schools, under its special Class C Grants Program, to help American educators find ways to cope with teaching problems growing out of the rapid advancement of the medical sciences. These grants ranged in size from $2,471 to $14,500 and were given on a one-year basis.

The Fund's grants were made possible through the generosity of some 1,925 corporations, which contributed $2,050,757, as well as through a Ford Foundation Grant of $1,305,374, under its "matching" arrangement with the Fund.

In July, the Fund announced the establishment of a Medical Research Program, through which contributions from united funds, community chests, voluntary health agencies, and other organizations would be channeled into basic medical research. The program will aim to help support the continuing search for new medical knowledge, and to increase the number of trained medical researchers in the United States.

The United Community Funds and Councils of America, whose local affiliates have expressed a desire to help support broad fundamental programs of basic medical research on a national level, have already agreed to support this new research program. Negotiations have been started with various voluntary health agencies for their support of the program. This expansion of the Fund's program will in no way affect its present campaign among corporations to obtain support for the teaching budgets of the medical schools.

In October, 1958, the Fund joined with the American Medical Association and the Association of American Medical Colleges in presenting the sixth Frank H. Lahey Memorial Award to Frank Abrams, former chairman of the board, Standard Oil Company of New Jersey, and a leading philanthropist. The award is given annually to a layman for "distinguished service to medical education."

Previous recipients of the award were: President Dwight D. Eisenhower, former President Herbert Hoover, Dr. Abraham Flexner, Colby M. Chester, and Alfred P. Sloan Jr.

To celebrate the opening of Medical Education Week in April, the Fund joined with the American Medical Association and the Association of American Medical Colleges in awarding a scroll to Robert E. Wilson, retiring board chairman, Standard Oil Company of Indiana, and a founding trustee of the Fund. Dr. Stanhope Bayne-Jones was among those who paid tribute to Dr. Wilson and who helped to focus attention on the continuing need for industry to help support medical education nationally.

The Fund reports that it is continuing its campaign to alert American corporations to the problems of medical education. There are still many things that corporation executives do not understand, but the Fund feels that, with time, this will be overcome and American industry will fully realize its obligations to the medical sciences.

In April, the Fund published its 24-page annual report, "Medical Manpower for Tomorrow," showing the close link between medical education and national security. In this report, the Fund discussed the need for creative research, new goals for medicine, why medical education is expensive, and industry's stake in strong medical education.

It is the Fund's hope that during 1959 it will continue to forge ahead in its goal of bringing financial support to the medical schools.

STUDIES ON THE INTERNSHIP AND RESIDENCY ASPECTS OF MEDICAL EDUCATION

During recent years there has been an increasing interest on the part of medical education, specialty boards, organized medicine, hospital administrators, and licensing bodies in the field of graduate medical education. With a few outstanding exceptions, relatively little interest was manifested during the first decade of the current century in this field of education by others than the leading clinical teachers and the young physicians seeking additional experience.

In regard to an obvious need existing at the time, the Council on Medical Education of the American Medical Association began listing hospitals in which internship opportunities existed about 45 years ago. The Council took leadership in setting up certain basic standards or "Essentials" as minimal requirements for internship training in hospitals seeking approval for them. These basic standards have been under constant review and revision in an effort to align them appropriately with current knowledge and trends in any given period. Through the years the American Medical

Association has maintained a field and headquarters staff to evaluate these programs in terms of these "Essentials" and to assist those concerned with this phase of medical education in maintaining suitable opportunities for young physicians during their period of internship training.

As the trend toward specialization advanced, the American Medical Association, through its Council on Medical Education and Hospitals, in cooperation with representatives of the specialty fields, undertook the task of developing basic standards or "Essentials" for graduate education and training beyond the internship. These have been prepared primarily as guides to assist those developing such programs and also to furnish information to individuals seeking training. They outline the basic principles common to all residency education and training and also indicate certain requirements in the different areas of specialization. Programs of residency training have also been subject to study by the field staff of the Council prior to evaluation and accreditation. During recent years, Residency Review and Conference Committees representing both the Council and Specialty Boards have cooperatively reviewed and revised the "Essentials" in keeping with the changing scene. Furthermore, this cooperative function has extended to responsibility for approval of residency training programs, subsequently listed by the Council in the annual Internship and Residency number of THE JOURNAL. One of the important objectives of this liaison has been to foster, in residency education and training, opportunities for total training programs in single institutions or through appropriate affiliations so that individuals seeking specialty training may be assured of reasonable continuity and upgrading rather than fragmented, isolated, and inadequate segments of experience.

In 1940, the Commission on Graduate Medical Education,[26] under the chairmanship of Dr. Willard C. Rappleye, with Dr. Robin C. Buerki as Director of Study, presented a report after three years of study. This report clearly pointed out the objectives and basic principles of the internship, the residency, and postgraduate medical education on the basis of the knowledge and needs of that period. The need for constant study and reappraisal, intelligent experimentation, and flexibility of thought and actions is reemphasized throughout this report, most of which with minor modifications is pertinent to the current setting.

There have been numerous studies of the internship since the report of this Commission. Several of these have been precipitated by action of the House of Delegates of the American Medical Association. For some years the Association of American Medical Colleges has conducted studies through a Committee on Internships and currently has a Committee on Internships, Residencies and Graduate Medical Education. Some of these numerous studies have been thoroughly objective, such as the comprehensive analysis and report of the Advisory Committee on Internships to the Council on Medical Education and Hospitals which was presented in 1953. This analysis, as well as most of the special studies prior to and following the report of the Commission in 1940, have been brought about through problems arising from the service versus the educational aspects of the internship and from concern over intern distribution.

Through the activities of the Council on Medical Education and Hospitals, the American College of Surgeons, the American College of Physicians, the Specialty Boards, the Association of American Medical Colleges, and other interested organizations, it has been possible to maintain some semblance of order in graduate medical education out of what might otherwise have resulted in chaos equivalent to or worse than that existing in medical schools at the turn of the century. There are, today, no clean cut lines of division between the clinical clerkship of the final year in medical school, the internship, the residency, and even some aspects of postgraduate medical education. In many situations the same facilities and patients are being utilized, and the same faculty personnel may be engaged in all of these areas of medical education. Furthermore, advances in knowledge have been of such magnitude that the years of education in medical school no longer qualify the physician to enter practice but, instead, furnish the initial plateau upon which he erects the additional education and training needed prior to qualification for general practice or a specialty.

It is natural, therefore, that there has been aroused interest and concern on all sides regarding the graduate aspect of medical education today. This was evidenced by certain medical schools some years ago when they instituted the requirement of a year of internship prior to granting the degree of doctor of medicine. It was essential that such internships be approved by the medical schools granting the degrees so that their products could be assured of experiences as interns which were known to be desirable. This situation no longer exists and currently all approved schools grant their diplomas on completion of the final year of medical school. Concern over the merits of some of the available internships some years ago was evidenced when the Association of American Medical Colleges requested deans to prepare lists of hospitals in their respective areas where there was ample evidence that internship opportunities were well organized and adequately supervised. The exchange of such information undoubtedly assisted in the general upgrading of internship opportunities, but it was found to be not entirely satisfactory and was discontinued.

On June 10, 1958, the W. K. Kellogg Foundation announced a grant to the Association of American Medical Colleges adequate to underwrite a study of the internship as it is presently operated in medical school controlled hospitals. This study should assist in the analysis and clarification of some of the current problems associated with this initial phase of medical education beyond medical school. Has the internship become outmoded in the medical school teaching hospital where student clinical clerks, residents, fellows, and postgraduate students are also participating? Can the internship in such a setting represent the education and training experience which has been its traditional objective? Will the proposed minimum two-year program as preparation for general practice fit into the medical school controlled hospital programs and will it be considered as an extended internship or an internship-residency? What is the relationship of internships to future specialty training? Do straight internships actually provide adequate perspective or do they primarily serve the restricted service and/or educational functions of departments in which they are offered? Is the rotating internship still as desirable as it has been considered to be, and, if so, what constitutes a genuinely sound rotating experience? Has the point been reached where it may be desirable to discard traditional terminology and develop new descriptive words to encompass a better concept of basic education and training beyond medical school? Undoubtedly, this comprehensive study of medical school controlled hospital internships will cast interesting and helpful light on some of these questions.

Another interesting and challenging study is being conducted by the Division of Research in Professions of the Bureau of Applied Research of Columbia University. This comparative study of the internship and residency from the sociological point of view has been made possible by a grant from the Commonwealth Fund. Those who have developed this project believe there are many reasons why it is important to study the internship and residency as part of the total process of medical training. In other words the study will, it is hoped, indicate which types of internships reinforce and extend the training experiences of medical school and which counteract it. What kinds of hospitals place interns and residents in positions to be able to do what they are supposed to do in such matters as rounding out their range of clinical experience under competent supervision; learning through doing what they have not done sufficiently before; developing through practice what has been partially learned through precept; their role in the team responsible for comprehensive medical care; and becoming increasingly prepared to advance constantly their own competence and ultimately advance medical knowledge? What values of the young physician prove most vulnerable to "unfavorable environment" during the course of internship and residency experience; which prove most resistant to deterioration; what environments are conducive to retention and extensions of earlier learning and what are those which lead to contrary results? This study will also direct attention to a "contextual analysis" and will deal with relative merits of internships and residencies in large and small hospitals, degree of emphasis on team-work during training, and many other facets of sociological interest and importance in this type of evaluation of graduate medical education.

In this dynamic and rapidly changing scene these studies of the internship and residency are timely and challenging. There is much that must be done to determine how education beyond medical school can be made of greatest possible value in preparing the physician of today and tomorrow for the responsibilities he must assume in medical care. Along with this basic challenge is that of developing and fostering those individuals who are to be the leaders of tomorrow in teaching and research as well as in the provision of medical care. Every phase of graduate education must be reanalyzed and readjusted as time goes on so as to avoid over rigidity and too narrow restriction of knowledge and to maintain reasonable flexibility and perspective. Medical education has as its primary objective the responsibility of providing the environmental situation conducive to the development of competent physicians skilled in providing the best of medical care. With all due regard to the many other facets associated with the various aspects of medical education, this basic educational objective should always be kept in mind and graduate medical education offered which will best insure its attainment.

NATIONAL ACADEMY OF SCIENCES–NATIONAL RESEARCH COUNCIL STUDY: POSTDOCTORAL EDUCATION IN THE MEDICAL SCIENCES AND RESEARCH: A PRELIMINARY REPORT

Postdoctoral fellowship programs form an important part of medical education. The Division of Medical Sciences of the National Academy of Sciences—National Research Council have undertaken a study of such fellowship programs and their impact on medical education. Dr. Arthur S. Cain Jr., the director of this study, graciously provided this preliminary report of the study for inclusion in the Report on Medical Education in the United States and Canada.

> The medical curriculum . . . has reached the limits of its capacity: it can contain no more. . . . It is clear that educationally we have come almost to an *impasse*, that the load not only cannot be increased, but that for the sake of good teaching it must be lightened and simplified. The medical student . . . must have a timely opportunity to ground himself in fundamental studies, and to learn how to think, how to observe, how to apply. Every pedagogical consideration, there-

> fore, points to the conclusion that the elementary underlying sciences must be learned by the student of medicine . . . before he enrolls himself in the professional school.

So wrote Henry S. Pritchett in 1912, two years after Abraham Flexner[27] had surveyed the shocking state of American medical schools. There were those who disagreed with Pritchett's estimate of the importance of basic scientific studies to the student of medicine. Some said elementary basic scientific knowledge was superfluous; it was enough to learn professional medical techniques well without understanding their scientific basis or questioning their scientific validity. Others seemed to be saying, "We must understand well the scientific basis of what we do to improve and expand our knowledge, and thus improve our clinical abilities."

Pritchett continued:

> Very interesting statements have recently appeared in American educational journals, calling attention to the fact that students who lack this (scientific) preparation appear to have made quite as good showing in certain medical schools as those who have it. Without going too far into an analysis of the facts that are advanced in support of this contention, it needs to be said that even were this true, it is beside the mark. It still remains certain that the youth who has not pursued these fundamental sciences does in the medical school an entirely different thing from the one who has been properly trained in them. Teachers of medicine readily admit that for students who have really mastered their elementary physics and chemistry and biology, medical education becomes a wholly different thing from what it is for those who have not gained that foundation, not only because the man so trained can begin at a different point, but also because he is familiar with scientific concepts, scientific nomenclature, and scientific methods of reasoning.

All were agreed that the medical curriculum in 1912 could hold no more, nor could the human brain assimilate rapidly accumulating knowledge. Nevertheless, curricula were expanded, premedical scientific studies were prescribed, and the basic sciences became an increasingly important part of medical education.

Today, the struggle for adequate insight and proficiency in the basic sciences of medicine seems at its zenith. The variety of scientific disciplines contributing to medical knowledge now extends into areas of physical and biological science not long ago little used by medical scientists. Clinical investigation has shifted from what was once called (by some) "applied" research to research of a very fundamental kind. Doctors of medicine and doctors of philosophy, especially those headed for careers in academic medicine and research but also increasing numbers of physicians who will make their careers in medical practice, seek ways to gain advanced basic scientific proficiency as an essential tool for productive careers. Through modern "fellowships," many of them find the way.

Fellowships in the medical sciences were born of the readjustments and turmoil of the first Flexner report (1910) and the need of medical school faculties for stronger basic scientific foundations. In 1921, when most of the proprietary medical schools had closed and medicine was finally within the universities, the Division of Medical Sciences of the National Academy of Sciences–National Research Council proposed that fellowships in the medical sciences be offered in national competition. The first such fellowships were soon established by the division and supported financially by the Rockefeller Foundation. That support has been continuous since the inception of the fellowships.

Those first fellowships gave young medical scientists an opportunity to improve their basic scientific backgrounds and sought to influence them toward careers in teaching and research. The popularity and success of the fellowships can be seen in the many such fellowships offered today.

In 1956, Dr. R. Keith Cannan, chairman of the Division of Medical Sciences, National Academy of Sciences–National Research Council, called attention to the variety and number of available fellowship opportunities and the rapid changes taking place in medical education and research. He proposed a study of postdoctoral fellowship rograms to determine their appropriateness to the developing needs.[28] As a result, the present survey of fellowships and similar training schemes, together with their impact on medical education and the medical schools, was undertaken. The financial support of the John and Mary R. Markle Foundation made the survey possible. The active cooperation of the Council on Medical Education and Hospitals of the American Medical Association and of the Association of American Medical Colleges has provided valuable assistance, and the National Institutes of Health, through a recent grant, aided in the rapid analysis of data by punch card methods.

Mrs. Lois G. Bowen, Professional Assistant of the Academy-Research Council and for some years responsible for the administration of the medical fellowship programs of the Academy-Research Council, has worked closely with the Director of the Survey from the beginning. The checking and preparation of thousands of questionnaires for analysis has been a complex problem for Mrs. Bowen and her assistants.

For the purpose of this survey, a fellowship is defined as financial support awarded to a doctor of medicine, doctor of philosophy, or scientist of equivalent education for full-time advanced study and training in basic medical sciences and research. The awards, with very few exceptions, are for a period of at least one year. The "junior postdoctoral research fellowship" is awarded to young scientists not yet established in a career and in need of more thorough training and experience in basic science and research methods. "Senior" and "advanced" fellowships are awarded to established medical scientists chiefly for concentrated research and study, usually for a period of three to five years. Occasionally, in the case of some senior scientists, they are awarded for shorter periods. Most junior fellowships exclude more than minimal teaching and clinical responsibilities. The fellowships studied in this survey were awarded in national competition. There are also other fellowships awarded by local agencies and institutions. These latter are not included in this report but will be discussed to a certain extent in the final report.

Table 3.—*Distribution of Applications and Awards of Fellowships by Doctoral Degrees*

Type of Fellowship Sought	Successful Applicants			Unsuccessful Applicants*			
	M.D.	Ph.D.	M.D. and Ph.D. held	M.D.	Ph.D.	M.D. and Ph.D. held	Totals
Junior postdoctoral	402	352	11	166	174	6	1,111
Senior or advanced	71	70	8	32	23	9	213
Either type (double application, would accept either award)	14	17	0	4	5	1	41

* Includes a few candidates who withdrew their applications prior to consideration.

Scope of the Survey

The survey was divided into six areas.

1. Opportunities for advanced training and experience in medical sciences and research available through the postdoctoral fellowships offered by more than twenty-two national agencies were studied. The purpose and regulations of these fellowship programs were analyzed to determine, insofar as possible, the kind and number available at junior, senior, and intermediate levels. Emphasis by the various agencies on specific scientific disciplines or disease categories and restrictions on the assumption of general academic responsibilities during the fellowship were also reviewed.

2. All applications submitted by doctors of medicine and doctors of philosophy for these fellowships during one test year (1955-1956) were analyzed. The curriculum vitae of each applicant, his area of research interest, and future career plans were included in material abstracted for study.

3. The chairmen of each of 11 departments of the United States medical schools were consulted by questionnaire for estimates of the balance between teaching and research in their respective departments and the supply and quality of applicants for budgeted vacancies on department staffs. The chairmen were also asked to complete tables giving educational background (by academic degree), postdoctoral [illegible] and information on financial support of department staff members. Similar information was also requested about postdoctoral fellows currently in the departments.

4. All current and past fellows of the 22 national agencies studied in parts 1 and 2 were consulted by questionnaire concerning their fellowship experience, present positions, plans for the future, attitudes toward academic and research careers, and clinical experience. Comments and suggestions were invited. Three questionnaires were used—one to all alumni of the 22 fellowship programs since 1945, plus all who held fellowships in 1939-1940; a second questionnaire to all 1957-1958 junior postdoctoral fellows; and a third to all 1957-1958 senior and long-term fellows. The three questionnaires were similar but altered to make them appropriate for their respective recipients.

5. All 1957-1958 interns and residents in primary teaching hospitals of every United States medical school were sent questionnaires. The questionnaires sought career interests, attitudes toward academic careers, research, private practice, and the nature and amount of additional study and training they deemed necessary. An evaluation of available training and fellowship opportunities and their estimates of the obstacles to acquiring additional training was also sought.

6. Finally, full-time members of all departments of anatomy, microbiology, biochemistry, pharmacology, physiology, medicine, and surgery were sent questionnaires. They were asked about academic responsibilities, especially teaching, research, and administrative loads. Educational backgrounds (by academic degrees, clinical training, and fellowship experience), sources of financial support, and other information was also requested. Additional departments will be included in this part of the survey.

Results

The results presented are selected for their appropriateness to this education number of The Journal.

One thousand three hundred and sixty-five doctors of medicine and doctors of philosophy submitted applications for junior or advanced fellowships in the medical sciences to one or more of the national agencies surveyed. Their applications were filed in 1955 and 1956 for fellowships the first year of which would terminate on or before Dec. 31, 1957. There were 48 more M.D.'s than Ph.D.'s among the applicants, and 35 applicants held both degrees. More than two-thirds of the applicants were awarded fellowships. The ratio between M.D.'s and Ph.D.'s in the successful group was approximately the same as in the whole group of applicants. A few applicants applied for both junior and senior awards, leaving the decision as to which

Table 4.—*Distribution of Incumbent 1957-1958 Fellows by Doctoral Degrees*

	Fellows, No.	M.D.'s	Ph.D.'s	Sc.D.'s	Two or More Doctorates Held
1957-1958 Junior fellows	463	262	207	3	9
1957-1958 Senior fellows	289	195	117	3	26
Past fellows					
1946-1956 incl., and 1939-1940	2709	1760	1122	34	207

was appropriate to the selection boards. Table 3 shows the distribution of applicants by degrees held, awards sought, and awards received.

Three thousand nine hundred and eighty-nine present and past fellows of the national agencies surveyed were sent questionnaires. These included all fellows since 1945, plus those who had awards in 1939-1940, and all 1957-1958 fellows. The 1957-1958 fellows are referred to as "present" fellows. Three thousand four hundred and seventy-four, or 87.1%, completed and returned their questionnaires. Of these, 3,461 questionnaires were coded and studied by punch card methods. Two thousand seven hundred and nine past fellows, 463 present junior fellows, and 289 present senior fellows were included. The distribution of M.D.'s, Ph.D.'s, and Sc.D.'s is shown in table 4.

All fellows, present and past, were asked to give their choice of careers without consideration of the economic rewards and then to give their choice under the realities of present day economics. The majority in all groups preferred a full-time salaried academic career if economic conditions could be disregarded, but approximately a third of these shied away from full-time salaried academic post's under the economic realities of academic life. Table 5 indicates the career choices of present and past fellows under conditions as they exist today and under conditions in which economic rewards would not be a deciding factor.

Table 5.—*Career Interests of Fellows*

Career Choice	Past Fellows		1957-1958 Present Junior Fellows		1957-1958 Present Senior Fellows	
	If economic rewards were equal	Under present economic conditions	If economic rewards were equal	Under present economic conditions	If economic rewards were equal	Under present economic conditions
1. Full-time academic post with good balance between teaching, research, and administrative duties	1,710	1,120	324	253	234	178
2. Full-time research with no other responsibilities	575	414	87	66	39	27
3. Clinical investigation and medical practice in a full-time academic position	545	530	75	96	37	54
4. Full-time private medical practice	71	344	9	33	Not requested	

Note: There are a few double choices included in the above figures. They usually represented indecision between numbers 1 and 2.

One thousand five hundred and fifteen past fellows were found to be in full or part-time academic positions. There were 226 professors, 125 associate professors, 571 assistant professors, and 194 instructors in this group. Five hundred and forty-nine were research associates and assistants or held other university titles. One thousand two hundred and nine past fellows were not in full-time academic posts, but 419 of these had held such positions in the past, while 790 had never held full-time academic jobs. All past fellows who did not hold full-time university positions at the time the questionnaires were completed were asked if they would accept such a position if assured of a suitable balance between teaching, research and administrative responsibilities in their work. Only 192 indicated that they would not. The faculty ranks for which those who said they would consider full-time academic careers thought themselves qualified are shown in table 6 and the minimum salary ranges they would accept are shown in table 7. The rank and salary expectations of present fellows are also shown in tables 6 and 7.

Table 6.—*Estimate of Their Faculty Rank Qualifications by Fellows Who Would Accept Full-time Academic Positions Under Suitable Work Arrangements*

	Past Fellows	1957-1958 Junior Fellows	1957-1958 Senior Fellows
Professor	217	7	73
Associate professor	456	35	147
Assistant professor	637	265	72
Instructor	148	175	7

Note: In some cases there was indecision between two ranks, usually at junior levels, and there is a small number of double choices included.

One thousand and eighty-five past fellows had no teaching experience in their fellowships, and an additional 1,216 had very little. Only 392 indicated significant teaching activities as fellows. Six hundred and fifty-nine who had had little or no teaching experience considered this a disadvantage and thought that fellowships should include teaching experience, but 981 disagreed with them. Present junior and advanced fellows who were engaged in at least some teaching in their fellowships considered the experience beneficial by more than ten to one.

The value of clinical training to the fellow concentrating on basic science and research experience has long been disputed by various segments of the medical fraternity. It is interesting to note that only 49 physicians among the past fellows have not served an internship, and most of them have spent at least one year in a residency. Almost half of the physicians among the past fellows are diplomates of medical specialty boards, and a majority of those who are not diplomates intend to seek certification.

Table 7.—*Minimum Salary Ranges Acceptable to Fellows Who Would Accept Full-time Academic Posts*

Range	Past Fellows	1957-1958 Junior Fellows	1957-1958 Senior Fellows
$6,000 or less	120	179	12
$6,000 to $8,000	297	174	51
$8,000 to $10,000	312	64	88
$10,000 to $12,000	148	13	48
$12,000 to $15,000	169	7	45
Over $15,000	127	0	14

Among present fellows, 22 physicians had not served internships and 72 had had no residency training. In table 8 the clinical training and specialty board status of present and past fellows is shown.

Table 8.—*Clinical Backgrounds and Specialty Board Status of Present and Past Fellows Who Hold the M.D. Degree*

	Past Fellows		1957-1958 Junior Fellows		1957-1958 Senior Fellows	
	Yes	No	Yes	No	Yes	No
Served internship	1,706	49	251	11	184	11
Served residency	1,541	203	217	45	166	27
Certified by a medical specialty board	845	903	23	239	88	105
Intends to seek certification	587	206	195	35	59	45

Two-thirds of the past fellows who had had internships or residencies thought that their clinical training had helped them profit from their fellowships. The clinical training, they indicated, had been beneficial to them in planning, conducting, and interpreting their research. Their comments often suggested that clinical training had made possible a clear idea of their research interests and the depth and breadth of basic scientific studies necessary for adequate pursuit of these interests.

Nine thousand four hundred and thirty interns and residents in the primary teaching hospitals of all United States medical schools received questionnaires, and 7,422, or 78.7%, responded. Of those responding, approximately 884 were graduates of foreign schools, and they will be considered separately in the final report of the survey.

Alternate questionnaires from graduates of United States medical schools (half of those returned, or 3,269) were coded and analyzed by punch card methods. The incoming questionnaires were filed so that half of the returns from each hospital were included in the total. Eight hundred and eighty-nine interns, 2,305 residents, and 75 clinical trainees were represented in this sample. The data here presented are taken from this 50% sample and reported in terms of numbers and percentages of 3,269. The questionnaires not analyzed by machine methods are being studied for comments and suggestions and included in the final report.

Table 9.—*Specialty Board Aspirations of Interns and Residents*

Specialty Certification to be Sought	Number
Medicine	682
Surgery	458
Obstetrics and gynecology	309
Pediatrics	285
Psychiatry and neurology	268
Radiology	164
Orthopedic surgery	156
Pathology	149
Ophthalmology	113
Anesthesiology	98
Urology	82
Thoracic surgery	65
Neurological surgery	61
Dermatology and syphilology	50
Otolaryngology	30
Plastic surgery	28
Physical medicine and rehabilitation	11
Proctology	2
Preventive medicine	1

Twenty-seven of the interns and residents held Ph.D. degrees, twelve the Sc.D., and 146 the Master's degree.

The interest of these interns and residents in advanced training in special clinical areas, advanced basic scientific study, and research training beyond any they had had, and teaching, was abundantly expressed in their responses. Only a handful, 105 out of 3,269, said they did not want to seek specialty board certification. Medicine and surgery, respectively, were the first two specialty choices. Obstetrics and gynecology, pediatrics, and psychiatry and neurology followed in that order (table 9). Only a few, 85, were undecided about specialty board certification.

Approximately two-thirds of the interns and residents wanted additional training in research regardless of their future career plans. Some preferred to gain this experience concurrently or intermittently with residency training, if possible. Others wanted fellowships and traineeships, and some were undecided as to the best method (table 10). Six hundred and thirty-six interns and residents planning careers essentially in private practice planned to engage in research along with their practices.

Table 10.—*Preferred Mode of Research Training*

	Number
Concurrent with residency	844
Intermittently with residency	856
Full-time research fellowship	324
Clinical traineeship	444

Only 245 in the intern-resident group, or 7.2%, indicated that they did not want to participate in teaching or research once they entered upon their careers, while 1,898 who plan careers essentially in private medical practice want to make teaching a part of their careers. In addition, 810, or 24.7%, want careers in full-time or essentially full-time academic positions. Almost a third of these (252) prefer full-time salaried positions and the rest "geographical" full-time. Only 33 interns and residents preferred full-time positions in a basic science department or a research institute.

Asked to evaluate some aspects of research fellowships and clinical traineeships, the interns and residents looked with disfavor by approximately four to one on regulations which exclude opportunities to maintain clinical proficiency during fellowship or traineeship. The exclusion of teaching opportunities was regarded with approximately the same disapproval.

Dissatisfaction with the breadth and depth of their basic scientific backgrounds was stated repeatedly in comments by the interns and residents, regardless of whether they were headed for academic careers or private practice. In answer to specific questions and in appended discussions of the subject, they expressed a desire and often a determination to understand and use the concepts and research methods of the basic sciences, physical as well as biological, in their future work. Statistical data on this subject and an analysis of the comments will be a part of the final report of the survey.

The final report from the survey from which this preliminary report is drawn will be made to the Medical Fellowship Board of the Division of Medical Sciences, National Academy of Sciences–National Research Council. The Board, under the chairmanship of Dr. Sam L. Clark, Vanderbilt University, has participated actively in the conduct of the survey, and the final report will provide a basis for the Board's recommendations to the Division on future postdoctoral fellowship activities.

REPORT OF THE SECRETARY'S CONSULTANTS ON THE ADVANCEMENT OF MEDICAL RESEARCH AND EDUCATION THROUGH THE DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE

On July 14, 1958, Secretary Marion B. Folsom released as a public document, the final report of the Secretary's Consultants on Medical Research and Education, entitled "The Advancement of Medical Research and Education Through The Department of Health, Education, and Welfare." Dr. Stanhope Bayne-Jones, formerly dean of Yale University School of Medicine, president of the Joint Administrative Board of the New York Hospital-Cornell Medical Center, and technical director of research, Office of the Surgeon General, Department of the Army, chaired the group of 10 prominent medical educators and industry research executives who participated in the study.*

When the consultants were appointed, Secretary Folsom indicated that among the reasons for this action were (*a*) the recent very rapid and large expansion of the medical research programs of the Department of Health, Education, and Welfare and (*b*) his concern that the medical research effort, which had contributed substantially to the health of the American people, should continue to make a maximum contribution based on wise policies, sound administration, and a competent scientific staff. The consultants were expected to look into such matters as (*a*) the activities of the Department of Health, Education, and Welfare in the fields of medical research and education, (*b*) the situation (state and needs) of medical research and education in the country as a whole, (*c*) the impact of the expanding research programs on medical education, (*d*) the availability of scientists, technicians, and facilities, (*e*) the relative emphasis given to research in the various disease fields, (*f*) the relative emphasis given to fundamental studies in the basic sciences generally, (*g*) the standards for approval of research projects, and (*h*) the relationship between federal and private research programs.

This study originally was designed to cover a two-year period, but at the request of the Secretary was shortened so that it might be submitted prior to his withdrawal from the Department of Health, Education, and Welfare in the summer of 1958. The report indicates that all of the consultants felt privileged to undertake this important assignment and that they were pleased to be able to give the Secretary their mature judgment on the matters with which they dealt. Secretary Folsom indicated his appreciation of the task commenting in the preparatory note that they had "performed their public service with distinction." He, furthermore, stated that the report was being made available as a public document in the belief that it will be of interest "not only to all those concerned with medical education and research, but those interested in the determination of policies and plans for research."

The report indicated the consultants believed that "expenditures for medical research in this country can and should be tripled to reach a billion dollars annually by 1970." To develop a medical research effort of this magnitude will necessitate an augmentation in the number of physicians and other scientists engaged in medical research from the current 20,000 to 45,000 by that date. The consultants indicated that funds for construction of medical schools will be needed "on a much larger scale than has heretofore been contemplated" and that even if large funds are provided "it seems certain that the number of physicians per 100,000 population will decline during the next 12 years." The report also states that "the expansion of medical research and education required in the national interest will be costly and should not be restricted by lack of funds." In 1957, for instance, total national medical research expenditures approximated

---

* In addition to Dr. Bayne-Jones, the special consultants were George Packer Berry, M.D., Dean, Harvard Medical School, Boston, Mass.; Thomas P. Carney, Ph.D., Vice-president, Research Development and Control, Eli Lilly and Company, Indianapolis, Ind.; Lowell T. Coggeshall, M.D., Dean, Division of Biological Sciences, University of Chicago, Chicago; Fred Carrington Cole, Ph.D., Academic Vice-president, Tulane University, New Orleans; Samuel Lenher, Ph.D., Vice-president, E. I. duPont de Nemours and Company, Wilmington, Del.; Irvine H. Page, M.D., Director of Research, Cleveland Clinic Foundation, Cleveland; Robert C. Swain, Ph.D., Vice-president in Charge of Research and Development, American Cyanamid Company, New York; Stafford L. Warren, M.D., Dean, School of Medicine, University of California Medical Center, Los Angeles; James Edwin Webb, President, Republic Supply Company, and President, Frontiers of Science Foundation of Oklahoma, Oklahoma City, former Director of the Bureau of Budget, and former Under-Secretary of State.

330 million dollars in comparison to the 900 million to 1 billion dollars which the consultants consider a conservative projection for 1970.

The consultants expressed the belief that the public interest would not be served if the ratio of physicians per 100,000 population falls below 132, which has been a relative constant during the past 30 years. To maintain this approximate ratio it is pointed out that from 14 to 20 average size medical schools should be developed to meet the needs of 1970 and that these will cost between 500 million and 1 billion dollars. Since there is a lag of approximately 10 years between the planning of a new school and the graduation of its first class, the consultants indicate that there will almost inevitably be a decline in the number of physicians per 100,000 between the present time and 1970.

The report states, "Unless there is a marked change in social philosophy leading to private gifts or state appropriations on an unprecedented scale, large federal appropriations will be required."

In discussing the support of medical research, the report suggests that the federal government should continue to provide about half of the funds needed so that by 1970 federal expenditures should increase from 186 to 500 million dollars. Last year industry contributed an estimated 90 million, private philanthropy 35 million, and endowment income approximately 19 million dollars. The committee projected for 1970 annual expenditures of over 300 million dollars from industry and over 100 million from private philanthropy.

The report covered many other areas, including an analysis of both physicians and Ph.D. potential additions in the field of medical research, the role of the Public Health Service and, particularly, the operations of the National Institutes of Health in this field.

This report should be carefully read and analyzed by thoughtful individuals, as the recommendations carry significant implications and challenges. As has been repeatedly pointed out in this and previous education numbers of The Journal, the present rapidly changing scene is beset with unknowns of many kinds. There are augmented needs in every area to meet the increased challenges of the growing population and the socioeconomic as well as scientific advances. These are not the type of challenges that can be successfully met with a "crash program" but rather necessitate sound, intelligent consideration. This study clearly implies the need for such objective analysis. Large financial resources, in themselves, carry no guarantee of solving these problems. Adequate financing makes the potentialities of any given situation better, providing they are realistic and attainable. The question can logically be posed as to whether all new medical schools in the future should be developed as elaborate research institutes or whether there is not a place for additional schools where the major focus is on sound education and more modest emphasis on research. Both educational and research aspects are vital to all institutions conducting medical education, but unless reasonable balance is maintained in planning for the future, the educational function of the medical school may be jeopardized through overemphasis on research alone.

PROGRESS REPORT SUBMITTED BY COMMITTEE ON PREPARATION FOR GENERAL PRACTICE

After a year and a half of study, the Committee on Preparation for General Practice on May 20, 1958, submitted a Progress Report to its three parent organizations, the American Medical Association, the Association of American Medical Colleges, and the American Academy of General Practice. The Board of Trustees of the American Medical Association subsequently presented the Progress Report as Supplement A in its report to the House of Delegates at their June (1958) meeting in San Francisco. In submitting this Progress Report the Committee expressed the hope that it would be carefully read and evaluated by all concerned and that any criticisms or suggestions be submitted to it for consideration prior to the preparation of a more definite final statement. The complete text of the report has been published in the Sept. 6, 1958, issue of The Journal as part of the Proceedings of the San Francisco Session and is referred to the attention of those who wish to review the complete text.

The report of this Committee merits serious study on the part of those interested in and concerned with basic or graduate medical education, specialty education and training, and licensure. After reviewing all aspects of current preparation beyond medical school, the Committee expresses the opinion that:

> The remarkable advances in medicine that have occurred and that will continue to occur have increased the difficulty and the complexity of general practice as well as of other specialty practices. The responsibility of the general practitioner is a heavy one. It demands knowledge, alertness, agility of mind, and a wisdom born of education and experience. It necessitates the possession of a sound knowledge of the fundamentals of medicine as well as a synoptic knowledge of the basic principles of special fields. In view of this, as well as the pattern that has been followed successfully in the specialty fields of developing graduate educational programs beyond medical school, the Committee recommends that a new graduate educational program for general practice be developed.

The proposed program constituting the final portions of the Progress Report is presented because of its inherent challenges to medical education and particularly to those who are endeavoring to offer graduate education and training in the field of general practice in keeping with current knowledge and needs.

The Proposed Program

In recommending a new graduate program for the general practice of medicine, the Committee believes that *primary* consideration should be given to an educational experience enabling the physician to provide medical care for all members of the family irrespective of age. After determining that the period beginning at the time of receiving the M.D. degree is the most appropriate one for a new plan of preparation for general practice, the Committee agreed to concern itself with a minimal program. It was considered best at the outset to avoid being compromised by programs presently in existence or by current limitations imposed by statutes or military obligations. This proposed program is designed to replace for future general practitioners, the current internship as well as existing residency programs in general practice.

The internship year as presently constituted cannot be considered as a component of this program for it would result in dividing it into two separate segments. The internship was designed many years ago to provide the initial contact with and responsibility for patients. Since the development of the clinical clerkship, it no longer comprises such initial patient contact but rather it is now considered as one of several graded steps toward the assumption of total responsibility for patient care. Further, there is now general agreement that the one-year internship alone is inadequate as preparation for the practice of medicine. The Committee believes the one-year internship encourages inadequate preparation for general practice.

The present values of the internship will be an inherent part of the proposed program, but cannot be separated out of it as a segment without weakening the greater values to be derived from dealing with the new program as a unified whole. The graduate program proposed as preparation for general practice is designed to be more comprehensive than the internship in regard to patient responsibility, educational content, and continuity of experience.

Under the existing circumstances, it is believed that a period of at least two years of formal hospital training following attainment of the medical degree is necessary in preparation for the general practice of medicine. However, time alone cannot serve as a valid measure of educational adequacy. *The two-year period would be minimal even where the other factors of educational quality and content are optimal.*

The graduate program of two years in preparation for general practice should be planned and implemented as a unified whole. Since the general practitioner is to provide continuing care, it is highly important that the preparation for this kind of practice be designed to assure every possible opportunity for the participant to study patients over relatively long periods of time. He should follow the patient, as necessary, in the outpatient service, when indicated in the home, and certainly from one hospital service to another. There should be a maximum continuity of assignment to specific services so that the program will stress education through continuing rather than episodic medical experience. Such a unified two-year program will permit and encourage the necessary progression of responsibility and content.

This two-year program should include a basic eighteen month period to provide experience in the diagnostic, therapeutic, psychiatric, preventive and rehabilitative aspects of internal medicine and pediatrics in a very broad sense. In addition to the basic period, the opportunity for training in obstetrics should be a requisite for all programs. Participants who plan to practice obstetrics are encouraged to spend the major portion of an elective six months in obstetrical training. For those who do not anticipate an obstetrical practice, the six month elective should be utilized for further training in other segments of the program. It is urged that the concept of unity be applied to the elective period to prevent unduly short assignments that would provide little educational justification.

Throughout the two-year program, the trainee should have experience provided by regularly assigned periods of emergency room service. The Committee believes that this should include training in the emergency and primary management of trauma and in minor surgery. (The working definition of the latter is that minor surgical procedures are those which in themselves have no expected mortality, require no medical assistants and, in suitable circumstances, may be performed satisfactorily outside the hospital.)

Because the care of the ambulatory patient is an important part of medical practice, provision of adequate opportunities for the study of outpatients is essential. This should constitute a part of the basic eighteen month period and may well continue through the other six months. It should include experience in medical or diagnostic gynecology.

Experience in the care of the new-born infant is considered an essential portion of the program.

The proposed two-year program should assure the opportunity for adequate preparation of the physician to provide medical care to all members of the family. Any physician planning to undertake obstetrics other than uncomplicated obstetrics, or surgery other than minor surgery, should have additional adequate training.

The Committee believes that such a two-year experience would furnish a sound base for further graduate medical education in any field. The Committee therefore recognizes that the thoughtful cooperation of specialty groups will be required to implement a sound program for preparation for the general practice of medicine.

This report outlines the minimal program under optimal circumstances. There will be those physicians who will elect further graduate education and such should be encouraged.

Finally, the general practitioner, like all other physicians, will be expected to pursue a continuing program of postgraduate medical education.

The Committee envisages certain further studies as required for the completion of its assignments. In view of the thoughtful cooperation of specialty groups needed for successful implementation of the proposed program, the Committee is holding formal consultations with such specialty groups as an essential preliminary to the more specific and detailed planning of the proposed minimal program. It expects to include consideration as to whether this program of preparation for general practice should be called an internship or a residency, or identified in some other manner. The Committee, in cooperation with the specialty groups involved, will give consideration to the type of recognition that may be developed for those individuals who successfully complete a part or all of this proposed program.

SECOND WORLD CONFERENCE ON MEDICAL EDUCATION

Planning has progressed satisfactorily to date for the Second World Conference on Medical Education, scheduled to be held in Chicago, Aug. 30 to Sept. 4, 1959. The general theme of this program, "Medicine—A Lifelong Study," will deal with the challenges of education beyond completion of basic medical studies. Since the first World Conference (London, 1953) was centered around consideration of the area of basic medical education, this projected conference will afford the opportunity to conduct similar exchange of viewpoints on problems and challenges associated with medical education beyond this level.

The Second World Conference will follow the general format which proved so eminently satisfactory at the London Conference in the use of initial and final plenary sessions with a series of four half-day interim panels. The panel sessions will devote considerations to (*a*) basic clinical training for all doctors, (*b*) advanced education for general and specialty practice, (*c*) the development of teachers and investigators, and (*d*) continuing medical education.

Arrangements are being made for preconference and postconference tours so that visiting medical educators from abroad may visit medical teaching centers. The initial response relative to participation on the part of outstanding foreign medical educators has been most gratifying and it is hoped that there will be a large attendance of American educators actively participating in making this a valuable and mutually stimulating experience for all. Those planning to attend should make their hotel reservations in Chicago well in advance. Headquarters will be at the Palmer House.

INITIAL TEST OF COOPERATIVE ANALYSIS OF PROBLEMS OF MUTUAL CONCERN LEADS TO PROPOSAL FOR PERMANENT LIAISON BETWEEN HIGHER EDUCATION AND ORGANIZED MEDICINE

In the 1955-1956 Annual Report on Medical Education in the United States and Canada[29] the "Conclusions and Recommendations of the Council on Medical Service Related to Private Practice by Medical School Faculty Members" was reported in detail. One of the recommendations was to the effect "that on request of a medical society and a medical school, the American Medical Association Board of Trustees establish, in cooperation with the Association of American Medical Colleges, a special committee whose function would be to investigate areas where there is friction between the medical school and the profession. Such a committee might (1) assure the continuation of liaison, (2) see to it that all data and facts are made available to all concerned, and (3) seek to resolve difference of opinion."

During April, 1958 occasion arose to utilize this mechanism as a result of a written request to the Board of Trustees from the president of the Medical College of Georgia, the president of the Richmond County Medical Society and the Council of the Medical Association of Georgia, together with the approval of the Chancellor of the Board of Regents of the University of Georgia. The Committee was appointed to study and mediate differences of opinion among doctors in Georgia regarding the policies of the Medical College of Georgia and its teaching hospital, the Eugene Talmadge Memorial Hospital. The Committee was appointed in cooperation with the Association of American Medical Colleges and consisted of seven physicians together with a staff member from the Law Department of the American Medical Association. The Committee spent three days on location analyzing the background of the problem, meeting with members of the local and state societies, the medical college and the Board of Regents of the University System, first individually, and finally collectively. After thorough discussion, oral agreement was reached in regard to four major areas of concern. This was then reduced to writing and subsequently signed by the presidents of the local medical society, the Medical Association of Georgia, the Medical College of Georgia, and the Chancellor of the Board of Regents of the University System.

The value of cooperation of this type in the objective analysis of the difficulties and misunderstandings which arise on occasion between medical schools and the profession has been clearly illustrated in this first instance of the application of the 1956 recommendation. The need for better liaison between higher education, representing the parent universities of which medical schools form components, and organized medicine has been apparent to many thoughtful individuals for some time and was also clearly highlighted in the Georgia situation.

Subsequent considerations have led to the proposal that it would be highly advantageous to all concerned to establish a "top-level" liaison between higher education and organized medicine to consider some of the mutual areas of concern that lie ahead. It has been proposed that this "top-level" liaison committee, to which reference has been made earlier in this report, consist of a representative from the presidents of universities in which medical schools exist, one from medical schools without university affiliation, two from the Association of American Medical Colleges, two from the Board of Trustees of the American Medical Association, and two from the Council on Medical Education and Hospitals, with staff representation from the latter three groups. It is anticipated that this committee will consider problems having mutual impact on medical education and medical practice such as the rapidly growing programs of prepayment for medical care, the increasing need for full-time faculty personnel to conduct teaching and research, and the ways and means where difficulties and/or misunderstanding created by the changing situations may be avoided or resolved. Such cooperative liaison carries great potential for avoiding in the future some of the difficulties which might have been obviated through more adequate objective intercommunications in the past.

REGIONAL INTERSTATE COMPACTS AND MEDICAL EDUCATION

The following resumes of the interest and activities of the Southern Regional Education Board, the Western Interstate Commission for Higher Education, and the New England Board of Higher Education were submitted for inclusion in this education issue of THE JOURNAL *to summarize the current status of these programs in the field of medical education.*

Southern Regional Education Board (SREB) and Medical Education

Over the past 10 years, the SREB program has had considerable effect on medical education in the 16 Southern states. Its impact is reflected both in the numbers of students and the amounts of money (table 11) that have crossed state lines under regional contracts since the beginning of the nation's first regional education compact.

Represented in these figures are significant benefits to states and institutions:

1. States which until quite recently did not have public medical schools assured medical training for sizable numbers of their citizens during a time when competition for admission was great.
2. Medical schools accepting contract students have received new money not available before the contracts, money which supplemented funds obtained from usual sources. Emory University School of Medicine, for example, has received to date some $775,000 under medical contracts, making it possible for Emory to avoid retrenching its instructional program during a period when it was reorganizing its medical school finances.
3. Meharry Medical College has received sufficient funds from the contracts to make it possible for it to continue medical training for many Negro students who might not otherwise have had an opportunity to enter medicine.
4. In some instances, the contracts have broadened the geographical area from which students were selected, with increase in quality of students.

As new medical schools were built during the past few years, the number of students under the contracts in medicine has diminished. If states use regional contracts solely to reserve spaces in out-of-state schools, the contracts will have limited use, since they do not provide capital funds for expanding the capacity of medical schools. However, some states with only one medical school eventually will be unable to meet student demands or needs for graduates. Expansion of some schools for interstate use will both save money and improve quality of training. Such selective expansion will be easier if the expanding schools have assurance that they will receive funds from contracts over a period of time in exchange for admission of quotas of students from other states. States will probably not be willing to contribute to capital costs of expansion, though the same effect can be achieved by setting the payments under contracts at figures which are high enough to cover instructional costs and amortization.

At the request of the Southern Governors' Conferences in 1954, SREB established a regional program to increase training and research in mental health fields, including psychiatry as well as other professions. The program, guided by a council composed of commissioners of mental health, professors of psychiatry, and other groups, has stimulated states to put more money into training and research, and has wrestled with reducing the personnel shortages which plague mental hospitals and clinics by encouraging more students to enter the mental health fields.

It has also been suggested that SREB study the possibility of using contracts (1) to stimulate expanded programs of postgraduate work in medicine and (2) as a means by which medical schools could increase quality of students through widening the geographic origin of student bodies. Neither of these two suggestions, however, has thus far gained widespread support among either medical educators or state officials.

Western Interstate Commission for Higher Education

The Western Interstate Commission for Higher Education (WICHE) is a regional education agency, organized and financed by 11 western states (Arizona, California, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Washington, Wyoming, and Alaska). The commission was set up by an interstate compact in 1950, at the initiative of the Western governors. WICHE is a fact-finding agency and a clearing house for ideas and proposals of interstate concern. Its task is to promote interstate approaches in higher education, particularly in the health sciences.

Table 11.—*Southern Regional Education Board (SREB) and Medical Education*

	Students, No.	Amount of Money Paid by States
1949-1950	174	$240,000
1950-1951	245	372,000
1951-1952	335	492,000
1952-1953	380	569,000
1953-1954	357	528,000
1954-1955	353	540,000
1955-1956	347	520,000
1956-1957	302	457,000
1957-1958	245	362,500
1958-1959 (estimated)	194	387,333

Medicine is a high priority item in the program of the commission. WICHE serves as a clearing house for a program whereby students from states without medical schools may attend medical schools in the area of the Western compact. Under this program, 85 medical students are crossing state borders this year to attend western medical schools. The student pays the regular in-state tuition; the sending state pays the receiving institution $2,000 per year in addition. The advantages run both ways —better educational opportunities for youth from "have-not" states and better financial support for existing medical schools.

In addition, WICHE is currently conducting a study of medical education needs and resources in the West. This comprehensive, region-wide study is under the immediate direction of Dr.

Dayton McKean of the University of Colorado Graduate School and will be reviewed by a representative advisory group before publication in 1958.

WICHE is active in related health science areas, notably nursing education and mental health training and research. In both areas, the commission has set up advisory councils, with representation from all over the West, to plan for a balanced growth—through complementary specialization of function—of Western professional and graduate education.

The New England Medical-Dental Education Program

Last February the New England Board of Higher Education proposed the New England Regional Medical-Dental Education Plan and recommended its adoption to the people of New England through their state legislatures. This plan is designed to assist and encourage the region's medical and dental schools in increasing the number of places for qualified New England students.

This action was taken because, in proportion to its population, fewer people from this region are entering these programs than from the nation as a whole. New England is not producing enough doctors and dentists from among its own residents to meet its own needs.

THE REGIONAL PLAN: Each New England medical school receives from funds appropriated to the Board from each of the participating states $2,500 per year for each student it enrolls from each state in excess of the number it enrolled from that state in 1956. This amount represents somewhat less than the average difference between what the student pays each year and the actual cost of instruction. Similarly, each dental school receives $1,500 and each state appropriates $1,500 for each student enrolled in excess of the number enrolled in 1956.

The plan has thus far been adopted by Maine, New Hampshire, Vermont, and Massachusetts. Supporting funds in amounts suggested by the Board were appropriated in these states except for New Hampshire, where a smaller amount was provided. The appropriations were: Massachusetts, $100,000; Maine, $20,000; New Hampshire, $8,000; and Vermont, $7,500. The sum recommended for Vermont was lower than for the others since under the plan that state, which supports its own medical school with tax funds, does not reimburse the University of Vermont for additional Vermont students.

The Board adopted a definition of residence based on those used by several publicly supported medical schools. During the past year an individual residence certificate was filed with the Board for every student enrolled in each of the region's medical and dental schools as of October, 1956, and for all students for whom New England residence was claimed as of October, 1957. The schools also have submitted certified class lists and statements of enrollment.

PROBLEMS OF RESIDENCE: When the given definition of residence was applied, the total number of New Englanders enrolled in 1956 was less than that reported earlier by the medical schools in an informal survey. Although many married students claim residence in the state in which they attend medical school, they do not merit this classification. Tabulation of the individual residence cards revealed that the number of residents enrolled in 1956 was 953, rather than 972, as was reported in the earlier survey.

IMPACT OF THE PLAN: The NEBHE plan was recommended by the Board last February and was not adopted by the state legislatures until several months later. Since by that time the incoming freshman classes had already been selected, the initial impact of the plan has not yet been felt. It will be a few years before its full effect can be ascertained.

COMPARATIVE ENROLLMENTS, *1956-1957:* The number of New England students in the region's medical schools in 1957 was 923 as compared with 953 for 1956, a 3.2% decrease.

The number enrolled in the dental schools increased from 333 to 345, a 3.7% increase.

In the medical schools there were increases for New Hampshire (8) and Rhode Island (1) and decreases for Connecticut (4), Maine (14), Massachusetts (20), and Vermont (1).

In dental schools there was a decrease for Connecticut (3) and increases for Maine (1), Massachusetts (2), New Hampshire (3), Rhode Island (4), and Vermont (5).

Four schools showed an increase of New England students: Dartmouth Medical School, 1; Harvard University School of Dental Medicine, 5; University of Vermont College of Medicine, 6; and Tufts University School of Dental Medicine, 7. Four enrolled fewer than last year: Boston University School of Medicine, 4; Harvard Medical School, 6; Tufts University School of Medicine, 21; and Yale University School of Medicine, 6.

FINANCIAL CONSIDERATIONS: Under the plan, payments are now due certain schools for enrolling a larger number of students from the four states which have adopted the plan, and the Board is now collecting and disbursing the funds.

The payments due from states which have joined the plan are: Maine, $5,500; Massachusetts, $41,500; New Hampshire, $29,500; Vermont, $10,000; and total, $86,500. However, since New Hampshire appropriated only $8,000, this amount will be prorated, and the schools will receive only 27% of the total due from that state.

SERIOUS CONDITIONS: Two serious conditions are already apparent. Since the number of bona fide residents in New England medical schools is smaller than was assumed, the enrollment of New Englanders in all schools in the country is probably less favorable than was previously supposed. Second, in most of the region's medical and dental schools New England residents are in competition for places with the best students from all over the country. Gaining admission at a time when facilities are limited will become increasingly less favorable for many qualified New England students than for those who live in states where sizable public institutions give first preference to their own residents and other regional students. A total decrease of 3.2% in one year is serious, and, in the case of Maine, the decrease of 14 students or 22.6% would seem to indicate a very critical situation.

If such conditions persist, it may be necessary for some New England states to consider additional plans so that qualified students will have opportunities equal to those in other sections of the country and so that future health needs of their residents will be met.

THE NATIONAL SOCIETY FOR MEDICAL RESEARCH

For a number of years the National Society for Medical Research has played a very important role in improving public understanding of the principles, methods, and needs of the biological and medical sciences. Its activities have become widely recognized, and its contributions to medical education, research, and medical care are of constantly increasing significance.

The following résumé describing the functions of the National Society for Medical Research has been prepared by its staff for this issue of the education number of The Journal.

The National Society for Medical Research founded in 1946 by America's medical colleges to deal with a symptom of public ignorance and misunderstanding of medical and biological science—the antivivisection movement—now functions to treat the disease itself. At first the society was wholly occupied with the stop-gap protection of animal research against immediate threats of legal prohibition and general harassment of medical laboratories by the antivivisection movement. This effort was quickly successful, and soon the society was able to turn a large portion of its capacity to long-range public education—though crises continue to arise from time to time.

There are many symptoms of public misunderstanding of medical science—superstition, quackery, resistance to inoculation, militant antidissection and antiexperimentalist movements, ignorance, and apathy toward the needs and problems of scientific research.

In attacking the disease, the NSMR administers preventive medicine in two principal ways. First, the society starts chain-reaction educational projects. For example, through the American College Public Relations Association the old blockade against full reporting of the role of animals in research was, for the most part, swept away. Use of animals in research ceased to be a dark and sinister secret.

Second, the NSMR initiated positive action programs to help medical science. The society formulated a model statute for the utilization of unwanted dogs and cats ordinarily killed in public dog pounds. Today three out of four medical schools in the United States receive their needed dogs and cats from this source.

The society instigated the $4,000,000 worth of libel suits against the Hearst press that helped end the Hearst campaign against experimental medicine.

The society gave assistance in forming the Animal Care Panel, an organization devoted entirely to the exchange of technical information on the care of laboratory animals.

Last year a committee of the NSMR began formulating plans for a national conference on the legal environment of medical science. Because of the hodge-podge of laws affecting medical science in the various states, the conference, scheduled for the spring of 1959, will aim toward producing a Uniform Legal Code for the Medical Sciences. Included in the model code will be laws governing property rights in dead human bodies and provisions for bequests of whole bodies or parts for bioanatomical studies and for the transplants of organs. Laws governing animal experimentation and disposition of unclaimed animals will also be part of the model code.

The conference will be the basis for extensive publicity on the practical problems and needs of medical science.

The National Society for Medical Research is supported by the medical schools, by virtually all of the professional organizations in medicine and biology, and by commercial organizations concerned with medical research. The society's work is public education. Its purpose is to expedite medical progress.

MEDICAL SCHOOLS

APPROVED AND NEWLY DEVELOPING MEDICAL SCHOOLS

Table 12 lists by states the approved four year medical schools and schools of basic medical sciences, indicating for each school, public or private ownership, year of organization, tuition charges, enrollment by class and other basic data. Similar data is presented in the same table for the newly developing schools and in table 13 for Canadian schools.

In the 1957-1958 academic year, there was no change in the number of approved four year medical schools in the United States (78) or Canada (12). There remain four approved schools of basic medical sciences in the United States while all of

† Part time and special students included in enrollment figures.

‡ Provisionally approved on the basis of full implementation of the first two years' program.

Tuition

University of California, L.A.
University of California, S.F.
University of Colorado
College of Medical Evangelists
University of Oregon
University of Utah
University of Washington

Residents of Arizona, Idaho, Montana, New Mexico, Wyoming, and Alaska who enroll under the Western Interstate Commission for Higher Education's student exchange program will pay the standard resident tuition.

Medical College of Georgia: Tuition includes breakage deposit, health, and activities fees.
Nonresident students of other approved medical schools are considered for advanced standing.
The nonresident tuition and fees are $755.

University of Michigan: Tuition subject to change.

Medical College of South Carolina: Non resident students of other approved medical schools are considered for advanced standing.
Nonresident tuition and fees are $1,592.50.

Premedical Requirement by Year

Cornell University: Three years, if degree will be granted in absentia.
Dartmouth Medical School: Bachelor's degree or three years and candidacy for the bachelor's degree.
University of Louisville: Degree preferred. Otherwise senior in absentia.
Vanderbilt University: Bachelor's degree or senior in absentia.
Vermont University: Four years and a Bachelor's degree.
Western Reserve University: Three years minimum.
Four years preferred.
Woman's Medical College: Four years preferred.
Baylor University: Four years with degree strongly preferred.
Bowman Gray School of Medicine: Degree strongly recommended.
Ohio State University: Four years or Arts & Medicine.

the Canadian schools present a full four-year program. It is anticipated that one of the schools of basic medical sciences, West Virginia University School of Medicine, will enroll students in the third-year class in its now developing clinical facilities by 1960. It will be eligible for approval as a four-year institution during 1961-1962.

Of the newly developing medical schools, the initial class at Albert Einstein College of Medicine has completed three years of study, while initial classes at the University of Florida College of Medicine and Seton Hall College of Medicine and Dentistry have completed their first two years of medical study. Provisional approval was granted Albert Einstein in the academic year 1956-1957; the University of Florida and Seton Hall were granted similar approval during this past year.

The University of Kentucky School of Medicine is the only other medical school presently undergoing active development. It is expected that the first class will enter this institution in the fall of 1960.

There has been an initial or continuing interest expressed in the potentiality of constructing new medical schools in Connecticut (Hartford as part of the University of Connecticut); Texas (San Antonio or Austin as part of the University of Texas); Arizona, Idaho, and Massachusetts (Boston as part of Massachusetts Institute of Technology). In the latter three instances initial interest appears to be directed toward the possibility of developing two year schools of basic medical sciences. Early but perhaps less well-formulated interest in the development of new medical schools is present in New York, Philadelphia, and Illinois.

CONSTRUCTION OF FACILITIES

During the year 1957-1958 there was an unusual amount of construction activity as 60 United States and 5 Canadian schools reported the initiation of new construction, the completion of construction, or the commitment of funds for construction to be initiated during 1958-1959. Thirty United States schools indicated the initiation of 41 construction projects, 26 United States schools completed construction of 29 projects, and 28 United States schools have funds committed for 35 projects with construction to begin in 1958-1959. One project was initiated by a Canadian school, five were completed at four schools, and in two institutions funds are committed for projects with construction to begin in 1958-1959. Table 14 presents estimates of construction and equipment costs for these projects.

Major construction completed during the past year in the United States includes seven new facilities or expansion and/or renovation of old facilities primarily for research, eight primarily for teaching, four clinical facilities, and three student dormitories. Howard and Indiana completed new basic science buildings and SUNY Syracuse completed a substantial addition to its old building which was also renovated.

Major construction initiated includes 15 new facilities or expansion and/or renovation of old facilities primarily for research, seven primarily for teaching, seven clinical facilities, and five student dormitories. Stanford initiated construction of its new basic science building and hospital in Palo Alto in anticipation of moving the medical school from San Francisco to the University campus. Johns Hopkins began construction of a new basic science building. The new hospital at West Virginia was begun anticipating expansion of the school to include the full four-year program.

Major construction planned for initiation in 1958-1959 with funds already committed includes 19 new facilities or expansion and/or renovation of old facilities primarily for research, eight primarily for teaching, seven clinical facilities, and two student dormitories. Tulane will begin construction

	Totals				

* Number of premedical years required after Junior matriculation in high school for admission to medical school.

† A, premedicine; B, medicine.

‡ In the case of Queen's Ottawa, and Toronto, where years of premedical college work is under the Faculty of Medicine in addition to the four years of medical school itself, the figure given admits to the first premedical college year of the faculty. To enter the four-year medical school program directly, two years of college are needed in addition to the figure given.

§ Degree in arts and sciences if college work is taken elsewhere.

‖ A very definite preference is given to those who have baccalaureate degrees.

¶ Intern and premedical figures not included.

of a large teaching and research building that will bring all departments together on one campus. Wayne plans to begin building a new basic science facility. New York University will get construction under way for its new hospital and Utah will undertake the construction of a new medical center building.

In Canada, Alberta completed a substantial expansion of its basic science building; British Columbia completed a pathology building and will begin construction of a new basic science building in the forthcoming year; and McGill will initiate construction of the first unit of its new medical center.

MEDICAL SCHOOL EXPENDITURES

In last year's report on Medical Education in the United States and Canada, specific quantitative data on medical school expenditures were not presented because of lack of assurance in regard to the completeness and validity of the information solicited in the annual questionnaire that serves as the basis for much of the material in these reports. There continues to be a need for a clearer concept of medical school costs. Because of his experience and continuing interest, Mr. A. J. Carroll,* Business Officer, State University of New York Upstate Medical Center, was asked to design the question dealing with medical school expenditures in this year's questionnaire. Mr. Carroll framed a question which solicited from each school actual expenditures for 1956-1957 and estimated expenditures for 1957-1958 under each of the items listed in table 15.

The data in table 15 are presented with more assurance in regard to completeness but nonetheless with considerable reserve as to the accuracy with which they present total medical school costs or estimates of costs. Because these figures have a different base than financial data presented in previous reports, they cannot and should not be compared with what superficially may appear to be similar cost figures in reports of other years.

The greatest doubt as to the accuracy in reflecting the grand totals of actual and estimated expenditures is the lack of uniform practices and terminology. For example, there is no generally accepted method within medical schools of accounting for direct costs of patient care in teaching hospitals. Undoubtedly in certain instances some such costs are included, and in others they are not a part of the individual school sums that are reflected in these totals.

In table 15 with each item there is an indication of the number of schools which reported sums under that item and the composite of which represents the total for that item. It is to be emphasized that the number of schools reporting under a given item reflects a mixture of both schools expending funds from that source and also accounting procedures that result in the expenditure of those funds being identified under that heading. One of many possible examples is cited for clarification. All schools receive funds from students as payment of charges for tuition and fees (*j*), yet 30 schools report no expenditure of funds under this item. Of the private schools not reporting, the expenditure would most always be included under the item for general university funds (*h*). Of the state schools not reporting, the expenditure could be and in some instances is included under general university funds (*h*), state appropriation (*f*) or state subsidy (*g*).

Under these circumstances, the data cannot be broken down validly to indicate the percentage of total expended funds that originated in any listed source. The sums presented under actual expenditures for 1956-1957 and estimated expenditures for 1957-1958, however, are based on sufficiently similar accounting practices within each school to make certain comparisons feasible.

TABLE 14.—*Estimates of Costs for Construction of Facilities*

United States Schools, 1957-1958	Estimated Construction Cost	Estimated Equipment Cost	Total
Construction Initiated	$63,660,000	$10,310,000	$ 73,970,000
Construction Completed	37,450,000	4,520,000	41,970,000
Construction Planned*	90,355,000	11,000,000	101,355,000
Canadian Schools, 1957-1958			
Construction Initiated	1,000,000	340,000	1,340,000
Construction Completed	5,530,000	270,000	5,800,000
Construction Planned†	4,300,000	250,000	4,550,000

* Funds already committed and construction planned for 1958-1959.
† Some schools reported equipment costs as part of construction costs.

Expenditures estimated for 1957-1958 were 13% greater (32 million dollars) than actual expenditures for 1956-1957. Increments greater than the estimated 13% in total expenditures are found in items for endowment income (*i*) 20%, grants and gifts for teaching (*c* and *d*) 19%, state appropriation (*f*) 19%, teaching expenses paid from medical service funds (*m*) 18%, overhead on grants (*k*) 17%, and grants and gifts for research (*a* and *b*) 16%. Estimates of expenditures from all other items (*e*, *g*, *h*, *j*, *l*, *n*, and *o*) are of a lesser increase than that estimated for the total.

Table 15.—*Medical School Expenditures**

Sources of Funds	Number of Schools Reporting Item	Actual Expenditures, 1956-1957	Number of Schools Reporting Item	Estimated Expenditures, 1957-1958

* Please refer to text under this same title.

The total actual expenditure for the median four-year school in full operation for 1956-1957 was between $2.370 million and $2.443 million. The total estimated expenditure for the median four-year school in full operation for 1957-1958 was between $2,871,000 and $2,877,000. The estimated total increase in expenditures for the median school amounted to almost $500,000. The range of change between funds expended by all 85 schools in 1956-1957 and their estimated expenditures was from $600,000 to more than $1,400,000. Eighty schools estimated increased expenditures, and only five estimated lesser expenditures.

In 1956-1957, 33 of 85 schools expended less than 2 million dollars. In 1957-1958, 28 of the 85 schools estimated expenditures under 2 million dollars.

It is pertinent to again point out that data presented for medical school expenditures cannot with present knowledge be translated into costs of educating medical students—or indeed any other single function of medical schools. These meaningful interpretations will be possible only when there is available a uniform, functional cost accounting system. The reader is referred to the section of this report on Medical School Financing for information in regard to a proposed study of medical school costs on this basis.

Canadian schools' expenditures are not presented since the returns from several schools did not contain adequate information.

FULL-TIME FACULTY POSITIONS IN THE UNITED STATES UNFILLED 1957-1958

Previous references elsewhere in this report have been made to the recognized needs for additional educational facilities in medicine to prepare increased numbers of physicians to provide health care to a rapidly expanding population. The creation of new and the expansion of existing medical schools pose difficult and serious problems in relation to site selection, construction of facilities, and financing. However, even if these problems were resolved and additional facilities were now available, they would be of limited value without adequate numbers of competent faculty.

The number of budgeted full-time faculty positions unfilled in 1957-1958 are presented in table 16. These data should excite real concern in all individuals interested in maintaining high standards in medicine for they reflect a sharp increase in what was before only a suggestive upward trend in the numbers of unfilled faculty posts (table 17). Unless this trend is broken, it seems unlikely that additional physical resources in medical education will be able to be staffed effectively.

A comprehensive study undertaken by the National Academy of Sciences promises to cast considerable light on this problem. Some of the early available information from that study appears in this report under title of "National Academy of Sciences–National Research Council Study: Postdoctoral Education in the Medical Sciences and Research; A Preliminary Report."

Table 16 indicates that 32% of all the unfilled positions are newly created posts. The number of unfilled newly created posts last year represented a larger segment (45%) of last year's total vacancies.

---

* See section of report titled Medical School Financing.

This shift indicates that this problem is not primarily related to a change in the basic nature of the educational program.

In view of the growing size of the problem of faculty recruitment, it is heartening to note that enrollments in advanced degree programs in the basic medical sciences (see section under this title) are increased over last year, since students in these programs represent the most assured pool of future faculty for the basic science disciplines. However, this at best can result in providing only a part of the additional faculty members needed.

It is to be emphasized that the vacancies existing in faculty posts presented in table 16 reflect only the numbers of faculty personnel required to maintain medical education at today's qualitative level and to produce graduates of the present quantitative order. Higher educational standards will not be solely related to increasing numbers of full-time faculty. Almost surely augmented numbers of competent teaching personnel will be an important factor in attaining advanced educational levels. It is certain that expansion of educational opportunities in medicine to meet the physician needs of an enlarging population can occur without serious harm to the quality of medicine taught and therefore of medicine practiced, only with a concomitant expansion of the body of full-time faculty.

GRADUATE EDUCATION IN THE BASIC MEDICAL SCIENCES

Because of the importance of acquiring well-prepared teaching personnel in the basic medical sciences, the last few annual reports on Medical Education in the United States and Canada have included information about graduate programs offered in the basic medical sciences and the number of students enrolled in these programs. The sharp increase in the number of unfilled full-time faculty positions (table 17) makes this information

* Check (✓) indicates an authorized program in which no students were enrolled during the year reported.

† An unknown number of these may be for doctoral degrees, since level of work was not specified.

ever more pertinent. It is to be remembered that general university departments in the biological fields offer graduate programs which serve as another source of teachers and investigators for medical school departments of basic sciences. Data in regard to such general university graduate programs are not available for reporting here. The study of the National Academy of Sciences–National Research Council described elsewhere will bring further understanding of present resources and future potentials for career teachers and investigators in medicine.

In table 18 are presented data for each school showing by basic science discipline the numbers of students enrolled who are working toward the masters or doctoral degree and postdoctoral students who are doing advanced study after having acquired a doctoral degree. Where checks (✓) appear in the table, the programs indicated are offered, but no students were enrolled during the year concerned. Table 18 also presents by school and by discipline the number of advanced degrees awarded in the basic medical sciences during the academic year 1957-1958.

Though not striking, there has been an increase in the total number of students working toward doctoral degrees in the basic sciences (table 19). Such a trend is not evident in enrollment figures for programs leading to the masters degree.

At the masters degree level, the largest number of enrollments occurred in microbiology, followed by biochemistry and physiology. At the doctoral level the largest enrollment was in biochemistry, followed by microbiology and physiology. The greatest number of both masters and doctoral degrees awarded was in microbiology, with biochemistry and physiology following in order.

schools are presented as part of table 18. Since this information was not available for previous years, it is not possible to draw comparisons.

TEACHING RESPONSIBILITIES FOR OTHER THAN MEDICAL STUDENTS

All of the medical schools in the United States, except one of the newly developing schools, have teaching responsibilities for students in addition to those in the basic medical educational program. In the case of eight schools, the additional teaching responsibilities include only interns and residents and in the case of three, include only practicing physicians in continuation education. The remaining 76 schools have responsibility for students in dentistry; nursing; pharmacy; x-ray and medical technology; arts and sciences courses; and such other students as those in physical therapy, occupational therapy, medical records, and medical librarianship in addition to medical students in the basic four year program, medical graduates in internships and residencies in the teaching hospitals of the schools, and physicians in continuing or postgraduate medical education programs.

Table 20 presents by school and student classification the educational responsibilities reported by the medical schools in the United States and Canada for students other than medical students in the basic program. Omitted from the table is a column portraying the number of enrollments by physicians in postgraduate courses inasmuch as the numbers reported did not appear to have a comparable base and thus did not seem to present an accurate picture of that educational responsibility.

The additional teaching responsibilities of the medical schools continue to increase each year. For the United States, such other students totaled at least 44,100, plus at least 20,500 physician enrollments in continuation courses. This represents a total of more than twice the number of medical students in the basic four year program. As has been pointed out previously, the totals given for other than medical students probably represent less than minimum real figures of the additional teaching responsibilities. For instance, a number of schools reporting zero nursing or arts and sciences students added that medical school faculty teach students in schools of nursing, social welfare, public health, as well as participate in the arts and sciences college programs. Only those interns in the one or two hospitals most closely related to each medical school are included, although some faculty time must be spent with interns and residents in other hospitals affiliated with the medical schools.

A major additional teaching responsibility, that of physicians in postgraduate educational programs, is omitted from the table because the figures did not seem, on the basis of other information the Council has, to have a comparable base among the schools. It will be recalled that in the Fifty-seventh Annual Report[30] a year ago, the analysis of 1,054 postgraduate courses in the 1956-1957 year showed

total physician enrollments of 34,913. Since 58.9% of the courses and 58.1% of the course hours occurred in medical schools or their teaching hospitals, there were probably at least 20,500 physician enrollments in these courses for a total of 31,094 course hours. Considering that medical school faculty personnel are involved in teaching in a majority of all postgraduate courses including those outside the medical school itself, this teaching responsibility is an important one not portrayed in the table 20 for the 1957-1958 year.

Totals	530	527	1,366	303	5,271	775	207	691	593

If one assumes that the schools were at least as active in courses for practicing physicians in 1957-1958 as was ascertained in the previous year, four categories of other than medical students account for more than two-thirds of the additional educational responsibility in United States schools in 1957-1958. These were physician enrollments in postgraduate continuation courses (at least 20,500), student nurses (10,252), residents (10,127), and arts and science majors (4,131). It should be pointed out that the numbers in the first and last categories just mentioned represent enrollments rather than individuals.

Relative to their total number of medical students in the basic four-year programs, the 12 Canadian medical schools had a proportionately larger educational responsibility for other students than did United States schools. In Canada, the other than medical students totalled 10,263, not counting the 413 students in premedical college work for whom three medical faculties (Queen's, Ottawa, and Toronto) had responsibility. The other students comprise almost three times the 3,685 medical students, not including physicians in continuation courses for which information was not comparable. The single group comprising about one-half of the other students were arts and science majors (5,271), while student nurses made up the next largest category (1,366).

The large numbers of other students for whom medical schools have educational responsibilities in addition to those imposed by medical students have significant implications on the personnel, budget, and facility needs of the schools. Unless these needs take into account the total teaching, research, and service responsibilities of each school, the educational value of any or all of the programs may be impaired.

SUPPLY OF ANATOMIC MATERIAL

The questionnaire this year to the medical schools included specific inquiry about the adequacy of supply of cadavers. In reply, although 72 schools indicated that the supply was adequate for the teaching needs of first year medical students, 13 of the 72 schools expressed reservations regarding the total adequacy of their anatomic material. Seven schools stated that the supply was barely or minimally adequate, one suggesting poor quality of material. Four schools stated that the quantity was satisfactory for first-year students but that it was inadequate for teaching surgical anatomy, seniors, and postgraduate courses. Two schools noted that the limited amount of anatomic material available increased the number of students per cadaver more than was desired, i. e., five or six students per cadaver as compared to the desired four, or four students per cadaver in a school where a 2:1 ratio is preferred.

Of the 13 schools in nine states and territories reporting an inadequate supply of cadavers, 5 commented that the state and county welfare agencies are providing burial to an increasing extent for the indigent who have ever received public assistance in any amount, thus decreasing the supply of anatomic material from the unclaimed and indigent deceased.

Requests or will-contracts disposing of the body to the medical school were mentioned by 11 schools, 5 of them being in California and the others in Florida, Ohio, Pennsylvania, Texas, and Wisconsin. Six of the schools cited bequests of bodies as providing an increasing supply of cadavers. One school in California relies entirely on the willed body program. Another school in that state expects to be able to do likewise in two years. A third school, which requires 50 cadavers a year and which would need 1,500 will-contracts to meet that need, received new will-contracts in 1957-1958 at the rate of 10 each week.

Considering the trend toward diminution in supply of cadavers from the unclaimed indigent population as well as the unprecedented response by the public in meeting the need by bequest in those states having statutes enabling such will-contracts, it is to be hoped that additional states will act to give legal recognition of bequests of bodies to medical schools.

Another factor among the schools which reported without reservation an adequate supply of anatomic material was the establishment and maintenance of understanding of the needs of the school as well as good relationships with morticians, social welfare agencies, and other public officials concerned with the disposal of unclaimed bodies. The development of such insights and helpful interpersonal relationships appears to be an important approach for better assuring an adequate supply of anatomic material. A medical school in one state having a potentially effective supply through law, but a lack of implementation by public officials, undertook to communicate to those officials the importance to the public of securing cadavers in order that the medical school could continue to meet its responsibilities in the education of medical students, physicians, and the advancement of medical science. That school reported that the cadaver supply, which had been relatively inadequate until 1954-1955, improved substantially to such an extent that a two-year supply was on hand in 1957-1958.

With few exceptions, those schools in states having a state anatomic board or committee established to provide cadavers to medical and dental schools report no lack of anatomic material.

In Canada, 10 schools reported an adequate supply of anatomic material, though 4 of those schools expressed reservations. One stated the supply was barely adequate and another school reported that it was adequate "only recently." A third Canadian medical school reported a shortage of female cadavers. A fourth, which prefers four students to one cadaver, stated that the available supply permits only a 5:1 ratio. Neither of the two schools reporting an inadequate supply proffered an explanation. Only one Canadian school, the University of British Columbia, cited bequeathed bodies as a source of anatomic material.

SUPPLY OF ANIMAL MATERIAL

A sufficient supply of healthy animals of various kinds is important not only to the educational activities of a modern medical school but to its research as well. Specific inquiry of the medical schools was made for 1957-1958 regarding the availability of living animals. The responses present problems that should concern the practicing profession, medical educators, and all others interested in the humane treatment of dogs.

Three schools in the United States did not reply regarding the adequacy of animal material. Of the 82 schools replying, 12 stated that the supply was frankly inadequate, while 69 schools reported with reservations that the supply was adequate in 1957-1958. The reservations included "adequate for teaching but not for research," "barely adequate for present needs," high cost, unpredictable delivery with seasonal shortages or inadequacy on specific demand. Nine schools of the 69 reporting an "adequate but" supply had one or more of these reservations.

The 12 schools reporting a frankly inadequate supply, chiefly of dogs, commented that the activities of antivivisectionist groups and their control of humane societies and local dog pounds were a major cause of the difficulty. This necessitated purchase of dogs from distant vendors, resulting in the delivery of ill kept dogs that were initially costly as well as expensive in terms of restoring the animals to health and in the limitation of research requiring healthy animals. It would seem that if the humane societies were really primarily interested in the welfare of dogs, they would not adopt attitudes and policies that make it necessary for medical schools to secure dogs from distant sources. The shipping of animals who are initially ill kept certainly must contribute further to their misery. If humane societies are concerned with the comfort of dogs, cutting off a local supply of healthy, though unclaimed, animals can only result in their shipment without adequate provision for proper feeding and care by the dealers who secure them. On the other hand, medical schools must be concerned with the health, comfort, and feeding of their animals because the results of tests are meaningless when the animals used are ill at the outset or are subject to pain.

All 12 of the Canadian medical schools reported an adequate supply of animals in 1957-1958, although one school commented about the "prohibitive" cost.

MEDICAL STUDENTS

ENROLLMENTS

For the ninth consecutive year, the number of students enrolled in approved and newly developing medical schools in the United States has established a new record high. Complete enrollment data for the individual schools is shown in table 12. Comparative data for this and preceding years are presented in table 21. In order to provide a true picture of medical education in the United States, table 21 and subsequent tables, unless otherwise noted, contain additions in the appropriate columns of the students in the newly developing schools: the University of Florida College of Medicine, Seton Hall College of Medicine and Dentistry, and Albert Einstein College of Medicine of Yeshiva University.

Table 21.—*Schools, Students, and Graduates in the Medical and Basic Sciences Schools in the United States, 1931-1958*

* Includes schools in development.
† Includes schools provisionally approved.

As was also the case in the previous three years, the figures in table 12 for enrollments by class as well as the total enrollments include the special and part-time students. The numbers of these students are tabulated for each school in the column after the total enrollment, although they are distributed in the enrollment figures in the prior columns of the table. A later section of this report categorizes for the first time the kinds of activities of part-time and special students.

The median total enrollment in 1957-1958 was 321, compared with 330 last year and 335 in the 1955-1956 year. The average total enrollment was

* Reference 31.

† Total number of applications filed by all applicants to all medical schools.

‡ Total number of individuals applying for entrance to Fall 1958 class was 15,791. Average applications per applicant were 3.9.

347, compared with 366 last year and 370 in the 1955-1956 year. The trend to smaller total classes noted last year appears to be supported by the current median and average. However, the students in the entirely newly developing schools more than compensate so that the number of total students is greater than ever.

Four schools each had a total enrollment of more than 600 (Tennessee, Michigan, Jefferson, and Illinois). Last year a fifth school, the University of Texas at Galveston, with an enrollment of 601, was also included in this group.

As was the case last year also, the University of Michigan and the University of Tennessee medical schools admitted more than 200 students into their entering classes in 1957-1958 (206 and 220 respectively). There were this year five additional schools with first-year enrollments of 150 or more students, though six schools were so categorized last year.

The total entering class was the largest yet enrolled (8,030), as tables 12 and 21 portray. However, there was not the large increase in 1957-1958 that occurred in 1956-1957 when the entering classes of the newly developing University of Florida and Seton Hall medical schools were included for the first time. Six schools had major changes in entering class size compared to the previous year; four increased and two decreased. The increases included Howard (33.3%), West Virginia (29%), College of Medical Evangelists (16.3%), and Miami (11.2%). The University of Texas at Galveston and Western Reserve University medical schools' first year classes decreased by 19.5% and 9.9% respectively. The median entering class numbered 86 students as compared with 84 in 1956-1957. The average first-year class in the four year schools was 97.2 compared with 94 in the previous year and 97 in 1955-1956.

TABLE 23.—*Number of Applicants to Medical Schools, 1948-1958**

Year	Individual Applicants, No.
1948-1949	24,242
1949-1950	24,434
1950-1951	22,279
1951-1952	19,920
1952-1953	16,763
1953-1954	14,678
1954-1955	14,538
1955-1956	14,937
1956-1957	15,918
1957-1958	15,791

* Reference 31.

Table 22, prepared by the Association of American Medical Colleges[31] lists by schools the number of applicants and applications to each of the schools for the 1957-1958 entering class. It should be noted that, although the numbers of men and women listed as applying to each school are individual applicants for each school, the over-all totals for the schools enumerate applications and not applicants. There were a total of 60,946 applications to all medical schools filed by 15,791 applicants, or an average of 3.9 schools applied to by each prospective medical student. For a complete and detailed study of applicants, applications, and acceptances for this class, the GEE study[31] should be consulted.

TABLE 24.—*Schools, Students, and Graduates in the Medical and Basic Science Schools in Canada, 1948-1958*

	Schools	1st Year	2nd Year	3rd Year	4th Year	Total	Graduates

*The remaining school of the basic medical sciences (Saskatchewan) became a four-year school with students in all years.

Although the number of applicants decreased a trifle in 1957-1958 compared to the preceding year, there was no significant change. The ratio of applicants (15,791) to places in the entering class (8,030) remained 1.9:1 as it was in the previous year. Table 23 presents the number of individual applicants to United States medical schools each year for the past 10 years.

The Canadian medical schools, as shown in table 13, also had in 1957-1958 a larger enrollment than previously of medical students, if the students in only the basic four-year program are counted each year to give comparable figures, excluding those in the premedical or required intern years. Comparative data for this and preceding years are presented in table 24. The median enrollment in 1957-1958 was 228 and the average 307, as compared with 224 and 304 in the previous year. Data on the applicants and applications to Canadian schools were not available for the 1957-1958 academic year in time for publication.

In 1957-1958, 82 United States citizens were enrolled in the first medical year in Canadian schools as compared with 4 Canadians enrolled in the first-year classes of United States medical schools. This is 10 fewer United States citizens in Canadian first-year medical classes than was the case in the 1956-1957 year. Even so, the favorable net balance of 78 United States citizens in the first medical year of Canadian schools represents the equivalent of another United States school having a class size larger than that of 28 of the United States medical schools.

ENROLLMENT OF WOMEN STUDENTS

Information by school on the number of men and women enrolled and graduated in the United States is shown in table 25. Woman's Medical

College enrolled only women, while Dartmouth and Jefferson continued to limit their enrollments to men. In 1957-1958, the 1,644 women enrolled comprised 5.57% of all enrollments, as compared to 1646 or 5.65% in 1956-1957. The proportion decreased slightly due chiefly to a larger total enrollment figure as only two fewer women were enrolled. The total women graduates increased, as predicted last year, by 25, comprising 5.1% of all graduates compared with 4.8% in the 1956-1957 class.

Excluding Woman's Medical College, the medical schools of four universities (University of Illinois, State University of New York in Brooklyn, Columbia University, and New York University), one more than in the previous year, each enrolled more than 40 women. Six other medical schools each enrolled more than 30 women: Howard, Harvard, Michigan, Western Reserve, Temple, and Tennessee. In five medical schools, women accounted for 10% or more of the enrollment: Howard, Boston University, New York University, Western Reserve, Puerto Rico. Women comprised 10% or more of the graduating class in four schools: Howard, Boston University, Wayne State, and Western Reserve.

The enrollments and graduates by sex in Canadian medical schools are also depicted in table 25. In 1957-1958, 259 women comprised 7.02% of the total enrollment, an increase of 23 or 917% over the 1956-1957 year. All 12 schools had women enrolled, although Queen's University had no women

graduates. The number of women medical students enrolled in Canadian schools has increased each year for the past four years, although it has not yet approximated the 276 women enrolled (7.5%) in 1953-1954.

Women graduates in 1957-1958 numbered 44, or 5.16% of the total graduates, a decrease of 20 as compared with 1956-1957, and the smallest number absolutely and proportionately since the 1951-1952 year when there were 36 women or 4.6% of the graduates.

Four Canadian schools (Toronto, McGill, Montreal, Laval) each enrolled 25 or more women. An additional three schools (British Columbia, Ottawa, and Saskatchewan) each enrolled 15 or more women. Two schools, the University of Toronto and the University of Saskatchewan, each enrolled women as 10% or more of their classes.

GEOGRAPHICAL SOURCE OF ENTERING STUDENTS

The residence of students at the time of their enrollment in the medical schools in the United States are shown in table 26, based on enrollment data for 1957-1958 from the medical schools.

This table indicates that 41% of all first-year medical students came from six states (New York, Pennsylvania, California, Ohio, Illinois, and Texas), as has been true for the past two years. The first-year enrollment of the 32 schools in these states also represented 41% of the total enrollment for the nation. Almost 38% of all medical schools in the United States are located in the same six states.

There were fewer than 20 first-year medical students from each of five states (Nevada, Delaware, Wyoming, Maine, and New Mexico) and fewer than 30 students from each of five other states (New Hampshire, Idaho, Montana, Vermont, and Rhode Island). Of these 10 states, only New Hampshire and Vermont have medical schools. The 74 students from the five states supplying the fewest medical students and the 123 students from the five other states represented only 2.4% of the total first-year class, 10 students and 0.17% larger than in the 1956-1957 academic year.

Table 27 lists the states in ascending order according to the number of enrolled first-year medical students per 100,000 population. The six states with the largest number of first-year students are distributed throughout this list, with one-half having less than the median number of students per 100,000 population (4.5) and one-half having more than the median number. As was true last year also, with the exception of Vermont and Wyoming, the other eight states having the smallest number of first-year students enrolled in medical schools had fewer students than the median number.

The over-all ratio of students per 100,000 population, excluding members of the armed forces, is unchanged from the 4.7 of last year.

There were seven schools, all state-owned, that enrolled as first-year medical students only those resident in the state in which the school is located. This appears to be a marked improvement as compared to 12 such schools in the 1956-1957 year, until the data in table 28 is noted. This table presents nonresident enrollments by numbers of schools in various proportion categories as well as numbers of students involved in the publicly-owned schools, as compared with four years ago when a similar analysis was developed. It will be seen that there is no significant change in the number of schools restricting their nonresident enrollment to less than 10% of the class, or in the number of nonresident students enrolled by the publicly-owned schools. Not counting the seven schools enrolling no nonresident students, the median proportion of the entering classes consisting of nonresidents was 8.1% in the publicly-owned schools and 50.9% in the privately-owned schools. The respective averages were 10.4% and 53%. The 57th annual report on Medical Education in the United States and Canada[32] presented a summary of geographical restrictive policies of the medical schools based on statements to the Association of American Medical Colleges that year.

As table 29 shows, a total of 37 entering students in United States schools came from the territories and possessions of Canal Zone, Hawaii, and Puerto Rico, and one came from Alaska. The 38 students entered 24 medical schools. Hawaii with 20 students and Puerto Rico with 16 students contributed nearly all of the 38 students. Of these areas, only Puerto Rico has a medical school.

Table 30 presents the geographic source of first-year medical students in the Canadian medical schools in 1957-1958. It should be noted at the outset that 82 students came from the United States (while only 4 students from Canada entered United States schools), representing a balance favorable to the United States of 78 students, as compared to a favorable balance of 84 students in 1956-1957, as was pointed out in the section on enrollments. The 82 United States students were distributed among 11 of the 12 Canadian schools. As in previous years, the majority of United States citizens (51 in 1957-1958 compared to 47 in 1956-1957) enrolled in McGill University. The four United States schools each enrolling one Canadian student in 1957-1958 were the College of Medical Evangelists, the University of Chicago, Johns Hopkins University, and the University of Kansas.

With the exception of the University of Alberta Faculty of Medicine, all other Canadian medical schools enrolled in the first medical year students not resident in the province in which the school was located. The proportion of such students varies from 2.5% to 64.7% in the 11 schools enrolling such

students with only 4 schools taking fewer than 10% nonresident students. Three provincially owned schools each enrolled more than 10% non-residents; two of the schools (University of British Columbia and University of Manitoba) each enrolled more than 20% of the entering class from outside the province of the school.

* Estimated July 1, 1957, total population excluding members of the armed forces stationed in each area. Current Population Reports, series P-25, no. 168, Dec. 9, 1957.
† States with no medical school.

Of the total of 215 out-of-province students enrolled in the 11 Canadian schools, 40 came from the British Commonwealth of Nations and other countries, and 82 came from the United States. Thus, a total of 93 Canadians enrolled in the first medical year class of Canadian schools outside their home province. The provincial schools accounted for 49.4% of these 93 Canadians as compared to the publicly-owned schools in the United States enrolling only 14.1% of the out-of-state United States students.

The Canadian provinces ranking highest as the residence of first-year medical students in 1957-1958 were Quebec and Ontario, accounting for 61.8% of the total class. However, 58.3% of the Canadian medical schools are located in those two provinces. Prince Edward Island, the only province in Canada having no medical school, was the source of the fewest medical students (7) in the entering class, although Nova Scotia was the source

of only 14 students. The Yukon and Northwest Territories, the source of no entering medical students, are sparsely populated frontier areas.

ATTRITION AND GEOGRAPHIC RESIDENCE RESTRICTIONS

The hypothesis was first suggested in the 55th Annual Report[33] that the attrition of students due to poor scholarship was significantly higher in publicly-owned schools than in privately-owned schools, at least in part due to the prevalence of geographic restrictions as to residence of students, which limited the population from which publicly-owned schools drew their first-year medical students. It was then suggested that the data in future years should be examined to provide additional information on this point.

Table 31 presents a comparison of first-year enrollments, applications, and attrition with poor scholarship by type of school ownership from 1954-1955 through 1957-1958. It is apparent that in each year, the publicly-owned schools had only one-fourth to one-fifth of the number of applications as did the privately-owned schools and had only 4% to 9% of their entering students resident outside the state in which the school was located. Although the proportion of the total entering classes enrolled in each was about equal, the number of students lost by poor scholarship was significantly larger each year in the publicly-owned medical schools. The chi-square of the differences in the numbers of students actually failing or withdrawing in poor academic standing in the publicly and privately owned schools as compared to what would be expected solely on the proportion of students enrolled in each is so large for each year as to make it highly unlikely that chance alone can account for these differences. The probabilities of this are given in the bottom lines of table 31.

In a similar table last year, the significance test was inadvertently applied to the proportions of students withdrawing rather than to the numbers of students. In consequence, it did not appear then

p, or probability, of these differences occurring solely by chance (one degree of freedom)	<0.001 (much less than 1 in 1,000)		Between 0.01 to 0.02 (about 1 in 90)		<0.001 (much less than 1 in 1,000)		>0.005 (almost 1 in 200)	

* Includes the three newly developing schools that are provisionally approved.

that the differences were as highly significant each year as they actually are. When the chi-square test is applied to the differences in numbers of students lost by poor scholarship in publicly owned versus privately owned schools, the probability of this happening by chance alone is not more than 1 in 90 and for two of the years is far less than 1 in 1000.

Another way of stating the problem is that their geographical restrictions on residence restrict application by and hence choice of as many highly capable students on the part of publicly-owned medical schools as by the more generally nonrestrictive privately owned schools. According to a study currently in progress by Dr. Helen Gee, of the Association of American Medical Colleges,[34] there is evidence that the Medical College Admissions Test scores are lower on the average for entering students in the publicly owned schools than for entering students in the privately owned schools. That test is taken by practically all applicants to United States medical schools. Such a difference in average scores of the two groups of students supports by different data the thesis suggested by the attrition from poor scholarship. It should be noted that, as in the case with all averages, the average scores of entering students in some publicly-owned schools are higher than are the average scores in some privately-owned schools. The important factor from both sets of data is not type of ownership but rather the presence or absence of any policy likely to restrict or discourage enough applications from among which the best classes of students can be selected.

TABLE 32.—*Comparative Analysis of College Records of First-Year Medical Students*

1.0-2.5	(C)	17	15	14.6	10.0	14.2	13.6	14.0	16.3	35.3

The policy of restricting most admissions to students who live in the state where the school is located has been evident for years in many of the publicly owned medical schools. Such a policy is advocated and defended by legislators as insuring educational opportunities for the sons and daughters of the taxpayers of the state, who support those schools.

The very policy and practice of so selecting entering classes that only a small proportion of students come from other states tends to preselect applicants to the disadvantage of the school and of society itself. Intelligence, high motivation, and other attributes desired by society and necessary in medical students are not distributed geographically. Capable students are discouraged from applying to a medical school across state lines if they are unlikely to be accepted because of where they happen to live. In consequence, some 12 privately-owned medical schools without restrictions on place of residence had 14 or more applicants per place in the entering class in 1957-1958 and an additional 7 privately owned schools had 12 to 14 applicants per place. Of the 18 medical schools having 9 to 12 applicants per place, 15 or five-sixths are privately owned. On the other hand, of the 16 medical schools that had only two to three applicants to each place in the entering class, all but one were publicly owned. Two of the three medical schools which had fewer than two applicants per place in 1957-1958 are state universities.

With their choice of an adequate applicant population from which to select limited by restrictions on residence together with pressures to fill their classes, many publicly-owned medical schools accept as students some individuals who are not as capable as might be some others who could have been accepted otherwise. This results in dual tragedy. The more apparent one is the failure of those students. The more important casualties, however, are the school and state itself for not having taken or had the opportunity to enroll the more capable students who did not apply or who were rejected solely because of state of residence. Some of those students may also have been lost to medicine itself.

Parochialism to this degree that is so disadvantageous both to capable individuals and to the broader interests and welfare of society itself should not be tolerated. It is to be hoped that state legislators and other public officials concerned with these matters will cooperate with university and medical school administrators in bringing the policies restricting admissions into a more realistic and socially useful focus.

COLLEGE RECORD OF FIRST-YEAR MEDICAL CLASS

Table 32 presents a comparative analysis of the premedical collegiate scholastic record of the entering classes in medicine in the United States each year since 1950-1951. As has been true since 1951-1952, about two-thirds of the first year medical classes had college grade averages of "B", while about one-fifth to one-sixth had college grade averages of "A" on entering medical school. Since 1954-1955, the proportion of students entering medical school with college grade averages of "A" and of "C" have been approximately equal, together comprising about one-third of the total entering classes.

In 1957-1958, 22 schools had more than the average proportion (17.7%) of "A" students in their entering classes, ranging from 19.6% to 68%. Nine of these were publicly-owned and 13 privately-owned schools. Seven of the 22 schools had entering classes in which students with "A" college records comprised more than 50% of the class. On the other extreme, 32 schools had more than the average proportion of "C" students (16.3%), ranging from 17.5% to 70.5% of students entering with "C" college records. Nineteen schools reported that one-fourth or more of the students in their entering classes had "C" college grade averages. Two of these are the same schools that also reported a significantly higher than average proportion of "A" students in their entering classes.

Although medical school admissions committees recognize the differences among colleges in the relationship of a given grade average to scholastic achievements, this should be pointed out to others who might consult table 32. For instance, scholastic achievement in one college that is awarded a "B" grade might in another college be given a "C" grade and similarly, though to a lesser degree, in the case of "A" compared to "B" grades. The scholastic record in college is one factor among many that are considered in the selection of medical students by the medical school faculties.

Table 32 also presents the premedical college grade averages of the 1957-1958 Canadian first year medical classes. The proportion of students having "A" college grades was similar to that in the United

States schools. In Canada, however, there was an average for all 12 schools of twice the proportion of students having "C" college records and hence one-third fewer students with "B" college records than in United States schools. Whereas in the latter only one-sixth of the entering medical classes had "C" college grade averages, in Canada more than one-third of the entering students had a college grade average of "C". Six of the 12 Canadian schools did have a higher than average (17.9%) proportion of "A" students in their first year medical classes, with one provincial school having 65% of its students entering with an "A" college grade average. Six Canadian schools had a larger than the over-all Canadian average of "C" students. In fact, three of the schools had more than 45% of their medical students entering with "C" college grade averages. Only two schools had fewer "C" students than the United States over-all average of 16.3% and these schools also had a significantly higher proportion of first year medical students with "A" grade averages in college.

TABLE 34.—*Comparison of Previous Years and the Current Year of Number and Proportion of Medical Schools Having Entering Classes Consisting Predominantly of Students with College Degrees*

	1954-1955		1955-1956		1957-1958	
Entering Students with Degrees, %	Schools of 81, No.	%	Schools of 85, No.	%	Schools of 85, No.	%
100	4	4.9	6	7.0	2	2.3
95.1-99.9	11	13.5	14	16.4	13	15.3
90.1-95	7	8.6	6	7.0	12	14.1
Total	22	27.0	26	30.4	27	31.7

Although no comparative data have been assembled, it is possible that Canadian college grades are significantly lower than are grades in United States colleges for similar academic achievement.

PREPROFESSIONAL ATTAINMENTS OF THE ENTERING CLASS

In 1957-1958, 79.2% of the entering class had four years of college and 72.1% had a degree on entering medical school. Those having only three years of college (85 semester hours or more) comprised 20.6% of the entering class. In 1956-1957, 77.5% of the entering class had four years of college, 73% had college degrees, and 22.5% entered medical school after three years of college. Table 33 presents the preprofessional attainments of the 1957-1958 entering medical class.

It thus appears that more students have a longer education before entering medical school than was the case in 1956-1957. Because this appeared to be a trend, a table was begun last year comparing the proportion of medical schools having entering classes made up predominantly of students holding college degrees. Table 34 brings that table to date, with the addition of numbers of schools in each category. It appears that a significant trend is occurring of more schools as well as a greater proportion of schools each year having entering classes consisting of more than 90% of students with degrees. Although four fewer schools in 1957-1958 had classes entirely composed of students with degrees, twice as many schools (six more) had first-year classes in which more than 90% of the students had degrees. This, coupled with a corresponding rise in the proportion of students having four years of college prior to entering medical school and a matching decrease in the proportion who have had only three years of college preparation, demonstrates a trend toward a greater college preparation before entering medical school.

The foregoing applies to the actual attainments of the entering class. Presumably influencing this are the minimum requirements for applicants as submitted to the Association of American Medical Colleges by the medical schools for publication each year in their guidebook.[35] Table 35 compares these requirements for the preceding two years, the current year, and for next year as most recently published. It is apparent that each year more schools require four years of college or a degree as their minimum stipulated to applicants. Although the 1957-1958 year appears to arrest this trend, the requirements published in the 1958-1959 guidebook for applicants to the September 1959 classes again shows an increase in the number of schools requiring four years of college or a degree.

The admission requirements of Canadian medical schools are obscured for those unfamiliar with the Canadian pattern of education in which the high schools have a grade 13 called senior matriculation, approximately equivalent to a first college year, as well as by three Canadian medical schools (Queen's, Ottawa, and Toronto) having the two premedical college years as a responsibility of the faculties of medicine. Taking these facts into consideration, table 13 shows that 10 of the Canadian schools require as a minimum the equivalent of three years of college before entering the basic four-year medical program, and the other two schools (Montreal and Laval) require a college

TABLE 35.—*Comparison of Admission Requirements, 1954-1955 with 1957-1958*

Stated Admission Requirement*	1954-1955	1956-1957	1957-1958	1958-1959
Less than three years college	1	1	1	1
Three years college	71	73	74	72
Four years college	8 }9	4 }11	8 }10	10 }12
Degree	1	7	2	2
Totals	81	85	85	85

* Each column taken from book "Admission Requirements of American Medical Colleges" (Including Canada), Association of American Medical Colleges, for the year stipulated. However, each column actually applies to next entering class. For example, the school's requirements in the column headed 1957-1958 were submitted by the schools to the Association of American Medical Colleges in the spring of 1957 for publication for guidance of applicants in the autumn of 1957 for the class of 1958-1959.

degree. Information on the preprofessional attainments of Canadian first-year medical students was not available in time for presentation in this report.

MEDICAL STUDENTS ADMITTED TO ADVANCED STANDING

A total of 271 students were admitted to advanced standing in United States medical schools in 1957-1958, 67 into second-year classes, 202 into third-year classes, and 2 into the fourth-year. All but 45 students, who came from foreign schools, transferred from approved medical schools in the United States and Canada. About one-half of the 226 students transferring from approved medical schools were accounted for by students from the four schools of the basic medical sciences.

The 115 students from schools of the basic medical sciences transferred to advanced standing into the third year (with one exception) of 25 United States medical schools and one Canadian school. Those six schools taking about two-thirds (65%) of these transfer students in 1957-1958 were Harvard (22), Medical College of Virginia (17), University of Kansas (13), Northwestern (9), University of Pennsylvania (8), and Southwestern (6).

In the 1957-1958 academic year, 27 medical schools in the United States admitted 45 students to advanced standing from other than approved medical schools in the United States and Canada, with 25 admitted to second-year classes, 18 to the third-year, and one to the fourth-year. Students from medical schools in four countries (Hungary, Switzerland, Netherlands, and Cuba) accounted for 33 or about 73% of the 45 students. Hungarian medical schools alone contributed 12 students, or 26.6% of the total. The remaining 12 students came from schools in eight countries in addition to the foregoing (Germany, Sweden, Italy, Czechoslovakia, Lebanon, Mexico, Poland, and England).

A total of 29 students were admitted to advanced standing in Canadian medical schools in 1957-1958, 10 into second-year classes, 18 into the third-year, and 1 into the fourth-year. Of the 29, 18 students or 62% came from foreign medical schools and 4 transferred from United States schools.

Seven of the Canadian medical schools admitted 18 students to advanced standing from nine foreign medical schools. Of these 18, 11 students or 61% came from Hungarian medical schools. The remaining seven students came from seven schools in six other countries (Switzerland, Scotland, Poland, Netherlands, Ireland, and Germany). The three Canadian schools having two premedical years under the administration of the Faculty of Medicine (Ottawa, Queen's, and Toronto) were excluded in the above analysis insofar as the second year was concerned because of the certainty in the case of three students in one school and the possibility with seven other students admitted to advanced standing in the second year that the premedical or college years were intended rather than the second medical year.

PART-TIME OR SPECIAL STUDENTS

Included in this group are those students who undertook in the 1957-1958 academic year a part-time course of study which will be given credit for the M.D. degree. Not included are those students who withdrew from all courses which would be given credit for the M.D. degree for the purpose of pursuing advanced study. The latter students will be discussed in the next section of this report.

There were a total of 226 part-time or special students in 47 United States medical schools in the 1957-1958 academic year. This was 0.76% of all 29,473 medical students. In order to determine the reasons for these students being in a part-time or special course of study, the medical schools this year were requested to enumerate such students by class in the 10 categories heading table 36. Almost 62% of all the part-time or special students are in their first two years. In fact, one-third are in their first year. It is gratifying to note that only one student was part time solely because of the necessity of earning money in outside employment.

One of the two largest over-all causes for students being part time or special (34%) was academic difficulty (in 18 schools), particularly in the first year (54% of those in this category). This would be expected, as the largest attrition has for years been in the first year of medical school. If one counts the number of students who withdrew because of academic failure or difficulty with those who were part time on this account to obtain a proportion of the total first-year class of 8,030 having serious academic difficulty, it appears that this amounts to 483 students, or 6% of the total first-year class.

TABLE 37.—*Attrition in the Approved* Medical Schools in the United States, 1957-1958*

Year	Enrollment	Failed	Withdrew, Poor Standing	Withdrew, Good Standing	Totals	Enrollment Lost, %
First Year	8,030	350	98	181	629	7.8
Second Year	7,504	153	19	65	237	3.2
Third Year	7,051	50	5	38	93	1.3
Fourth Year	6,888	8	1	13	22	0.3
Totals	29,473	561	123	297	981	

*Includes the three newly developing provisionally approved schools.

Exactly equaling academic difficulty as the cause for part-time or special study is the number of students undertaking advanced study, either for a degree or unrelated to an M.S. or Ph.D. Those 78 students in 18 schools comprise 34.5% of the 226 part time or special students. More than three-fourths of these 78 students were in their second (52.5%) and third (25.6%) years. It should be noted that these figures do not purport to show and should not be interpreted to mean that only 78 of 8,030 medical students undertake advanced study. It simply accounts for one reason for medical students being in special or part-time programs.

In the next largest category are those medical students who are also teaching, usually in a basic medical science in which they have had advanced study. More than 85% of those 41 medical students in 21 schools hold advanced degrees, with about 70% of them Ph.D. degrees and 15% M.S. or M.A. degrees.

Except for five students in the first two years who had had certain required course work elsewhere, the remaining 23 special or part time students are accounted for as stipulated in the footnote to table 36. Particular experiments in medical education by two schools (University of Buffalo and University of Vermont) engage five students, and illness or its effects was the problem with five students. The other 13 students were in part-time or special study for a variety of reasons.

There were only two part-time or special medical students, both men, in Canada. Each was in the second medical year of the University of Saskatchewan. One was teaching as a Ph.D.; the other had had previous academic difficulty.

STUDENTS WITHDRAWING FOR ADVANCED STUDY

Not included in the total of 29,473 medical students in 1957-1958 were 97 students who entirely withdrew in 43 United States schools from all M.D. credit courses to pursue advanced study. All but one of these 97 students withdrew during their first three years of medical school; 84.5% were in their second and third years. The advanced study was toward a graduate degree (M.S. or Ph.D.) other than the M.D. by 47 students (48%), though not degree related in the case of the other 50 students. At least 78 students (80%) of the 97 were pursuing study in the traditional basic medical science disciplines; in addition, one student's field was "biological sciences" and another student's field was given as "nuclear science." Only three students had withdrawn for study in a clearly clinical field (psychiatry). It is not possible to categorize accurately the field of study of 14 of the 97 students because the field as given was "USPHS Fellowship" or "medicine" or "surgery", for example. Considering that 10 of the 14 students withdrew during their second year, it is probable that their fields of advanced study were essentially basic science rather than clinical.

As noted in the section on part-time and special students, neither those students doing advanced study nor students withdrawing from M.D. credit work, nor both together, represent the number of medical students pursuing advanced study, nor the number of schools whose educational programs are sufficiently stimulating to the spirit of scientific inquiry in medical students. The request this year to medical schools for information was not designed to elicit such information but rather to account more fully than previously the reasons for students withdrawing for advanced study and for their being in part time or special M.D. credit programs. It should be recognized that other medical students, perhaps many other students, are pursuing advanced study and research during their unscheduled periods while they are full time medical students.

TABLE 38.—*Comparison of Attrition First-Year Medical Students*

Year	Total First-Year Class	Students Leaving		Students Failing*		Students Leaving, Other Reasons†	
		No.	% of Class	No.	% of Class	No.	% of Class
1954-1955	7,576	418	5.5	257	3.39	161	2.12
1955-1956	7,742	480	6.2	324	4.18	156	2.01
1956-1957	8,014	544	6.8	368	4.59	176	2.19
1957-1958	8,030	629	7.8	448	5.57	181	2.25

*Failed or withdrew in poor academic standing.
†Withdrew in good academic standing for all other reasons.

In each of three Canadian medical schools, one student withdrew from all M.D. credit work in 1957-1958 to pursue advanced study. Each of the three students favored a different field, although all were studying in one of the traditional basic medical science disciplines. Two of the three were in their first medical year; the other withdrew from the second medical year. Two of the three students were in nondegree related advanced study.

ATTRITION OF MEDICAL STUDENTS

Table 37 presents attrition by class and cause of students lost to medicine in 1957-1958 in United States schools. It was hoped that after receiving responses from the medical schools to identical questions regarding student attrition each year for four successive years, the attrition in a single class of students throughout their four years could be obtained on a national basis. Such did not prove to be the case. It appears that this can be done only on the basis of individual student records rather than on the numerical totals reported.

There has been in 1957-1958 an increase in the number and proportion of students lost because of academic difficulty in the first three years and a decrease in the number and proportion lost for this cause in the fourth year, as compared with previous reports. However, the number of students withdrawing for any cause in the fourth year is too small to warrant conclusions in regard to trends as to cause. With the exception of the 1956-1957 year, when an unusual number and proportion of fourth-year students withdrew in poor academic standing, there has been no significant change for fourth-year classes since 1954-1955, when this information was first regularly compiled.

In 1957-1958, as in the previous three years, about two-thirds of all student losses were in the first-year class. The current data show that 71% of these losses were due to failure or withdrawal in poor academic standing, as compared to 67.6% in the previous two years. The second-year class in 1957-1958 had 72.5% of its losses from this cause, as compared to 64% in 1956-1957 and 62% in 1955-1956. In the current third-year and fourth-year classes, 55.6% of the students lost, failed, or withdrew in poor academic standing, compared to 67% in 1956-1957 and 55% in 1955-1956.

TABLE 39.—*Attrition in the Approved Medical Schools in Canada, 1957-1958*

Year	Enrollment	Failed	Withdrew, Poor Standing	Withdrew, Good Standing	Totals	Enrollment Lost, %
First	1,011	49	2	34	85	8.4
Second	916	35	0	9	44	4.8
Third	928	9	0	6	15	1.6
Fourth	830	1	0	4	5	0.6
Totals	3,685	94	2	53	149	...

Examination of attrition data for the current year and for the past three years shows an increasing number and proportion of students in both first-year and second-year classes withdrawing from medical school. A comparison for the first-year classes is presented in table 38, although a table showing entirely similar trends could be presented also for second-year classes since 1954-1955. It is apparent that the increase in attrition is entirely occasioned by an increasing number and proportion of students failing and withdrawing in poor academic standing. The reason for this is not evident from the data available at this time. That it is not due to earlier identification of poor students is apparent, because if that were a major factor, one would expect a decline of attrition from this cause in second-year and/or third-year classes. Such is not the case. Rather, they have shown similar trends of rising numbers and proportions of students failing and withdrawing in academic difficulty since 1954-1955 to the present. On the other hand, the number and proportion of students withdrawing for all other reasons has shown no significant change for first-year to fourth-year classes since 1954-1955. It has been, in proportion of the total class sizes each year, from 0.6 to 1.0% for second-year classes, about 0.5% for third-year classes, and about 0.21% for fourth-year classes.

TABLE 40.—*Estimates of Median Student Expenses per Year**

Item	Privately Owned Schools (N=45)	Publicly Owned Schools (N=40) Resident	Publicly Owned Schools (N=40) Nonresident
Tuition and fees	$1,002	$500	$836†
Room and board (minimum)	806	765	765
Books and supplies (not including microscopes)	150	130	130

*Reprinted with slight modification from "Admission Requirements of American Medical Colleges (including Canada), 1958-1959" published by the Association of American Medical Colleges, Chicago.

†Excluding one school that accepts no nonresidents in the first-year class; no nonresidents are accepted at six schools.

Table 39 presents by class and cause the attrition of students in the 12 Canadian medical schools for 1957-1958. Comparable data was not presented in previous years. Of the total students lost to medicine for all causes in all classes, 57% occurred in the first-year class and 86.6% in the first two years. Two-thirds of these were due to failure or withdrawal in poor academic standing. This is comparable with, although not exactly the same as, the experience in United States schools. Although, as in the case with United States schools, Canadian medical schools have half of their students lost to medicine in the third and fourth years withdrawing in good standing, both the numbers (10) and proportion (0.56%) of the total classes are small for such attrition.

STUDENT EXPENSES

Table 40 shows the most recent annual expense estimates for medical students at United States medical schools, based on information secured by the Association of American Medical Colleges. As that association pointed out,[36] the figures can be regarded as only rough budget goals. They are subject to change even within the next year, and there is a considerable range within each of the categories in the table. With tuition and fees, for example, the range is $592 to $1,280 for privately owned schools, $120 to $900 for residents in publicly owned schools, and $416 to $1,300 for nonresidents in publicly owned schools. Tuition in the individual schools is given in table 12 for United States schools and in table 13 for Canadian schools.

TABLE 41.—*Canadian Tuition Fees*

	Publicly Owned (N=7)		Privately Owned (N=5)	
	Resident	Nonresident	Resident	Nonresident
Average 1st Year..........	$506.68	$535.25	$578.80	$655.80
Average 2nd Year..........	529.54	558.11	Same	Same
Average 3rd Year..........	536.68	565.25	Same	Same
Average 4th Year..........	558.11	566.25	Same	Same
Over-all average..........	527.75	566.32	578.80	655.80
Over-all median..........	531.00	531.00	545.00	630.00

It should be emphasized that the living expenses of individual students vary greatly, depending upon their family responsibilities and upon their spending habits.

Table 41 presents by medical school year the average tuition charges in the Canadian medical schools as well as over-all average tuition and over-all median tuition. In order to present meaningful figures, it is necessary to present the averages in the publicly owned schools by year because in three schools (Alberta, Toronto, and Saskatchewan) different tuition fees are charged in the four years of the medical school. Similarly, the over-all averages and medians were obtained by treating each of the four years in each of the 12 schools as a separate tuition figure. This was not necessary in the case of the privately owned schools, which uniformly charge the same fee in each of the four years. The designation private ownership has as much or as little meaning relative to sources of financial support for at least two of the five Canadian schools so categorized as does ownership versus sources of support in many United States schools classified as privately owned.

Table 13 presents tuition charges by individual school. It will be noted that the ranges in tuition are not as broad in Canadian schools as compared to United States schools. Tuition in the publicly owned schools is comparable in the two countries. The lower tuition in the privately owned schools is significant, even allowing for differences in dollar value and purchasing power in the two countries. The range in Canadian publicly owned schools is $391 to $585 for residents, and $391 to $731 for nonresidents. The spread for privately owned schools is $520 to $750 for residents and $520 to $834 for nonresidents.

Estimates of other student expenses, such as for room and board, books, and supplies were not available regarding Canadian students in time for publication in this report.

SCHOLARSHIP AND LOAN FUNDS, 1957-1958

In the questionnaire which largely serves as a basis for this report, information was sought pertaining to the usage of scholarship and loan funds. A large body of data, probably more detailed and complete than has been recently available in regard to usage of these funds, was collected, and pertinent aspects of these data are presented here. Although this material is believed to be nearly complete as it concerns scholarship and loan funds administered in some manner by the medical schools, there is such a variety of sources of funds, particularly for loans, that this study should not be considered as encompassing all scholarship and loan funds utilized by medical students during the 1957-1958 academic year.

The data presented in this section of the report excludes the medical schools still in development. Table 42 depicts some major characteristics of scholarship usage. Because of apparent gross differences in United States schools by the type of ownership, data are presented according to this division as well as for United States schools as a whole.

Although enrollment is almost evenly divided between publicly and privately owned United States schools (approximately 14,000 and 15,000), of the nearly one and a half million dollars expended for scholarships in 1957-1958, only 25% was utilized in publicly owned schools as opposed to 75% in privately owned institutions. This ratio is necessarily reflected in the amount of expended scholarship money artificially distributed over the total student enrollment. In addition, the average dollar value of scholarships, the number of scholarships granted, and the percentage of the total enrollment holding scholarships are all significantly greater in the privately owned schools.

TABLE 42.—*Utilization of Scholarship Funds, 1957-1958 (82 United States and 12 Canadian Schools)*

	United States Schools		All United States Schools	Canadian Schools
	Public (39)	Private (43)		
Scholarship funds expended.....	$358,638.00	$1,099,229.00	$1,457,867.00	$166,432.00
Scholarship funds expended per students enrolled....	$26.64	$72.78	$50.30	$45.16
Average dollar value per scholarship......	$391.10	$568.67	$511.53	$196.73
Average tuition charge.......	$487.87	$993.02	$752.75	$540.94
Number of scholarships granted	917	1,933	2,850	846
Percent of enrollment holding scholarships	6.5	12.8	9.9	23.0

On initial thought it might be presumed that the considerably larger scholarship sums distributed over a greater proportion of the student body would render private schools a distinct financial advantage to medical students. However, this advantage is partly offset by higher tuition charge. As indicated in table 42, the average tuition charge for private schools is more than $500 greater than the average for public schools. Of the total tuition charge of

$21,800,000 for the academic year 1957-1958 for all students in United States medical schools, 15 million dollars was assessed by privately owned schools and $6,800,000 by publicly owned schools. Scholarships awarded by private schools reduced tuition charge paid by students to $13,900,000. In public schools, scholarship awards reduced student tuition payments to $6,400,000. The over-all tuition charge borne by students was reduced by scholarship awards for $21,800,000 to $20,300.000.

In an effort to create what might be called an index of scholarship granting performance, United States medical schools according to type of ownership were arrayed in rank order by expended scholarship dollars distributed over the total student enrollment. In effect, the school of the highest order in this array expended in 1957-1958 most scholarship dollars per student enrolled. It is to be emphasized that these data are presented without specific knowledge of the degree to which real student needs were met and must be considered as representing an impersonal relationship between scholarship dollars expended and the number of students enrolled.

Table 43 summarizes this array of scholarship awards "Performance." Although schools are not identified by name, any institution desiring to know where it stands in the rank order can obtain this information by writing to the Council on Medical Education and Hospitals. In table 43, the dollars expended for scholarships divided by the number of students enrolled are presented for the upper, middle, and lower five schools in the rank order. The figure for the median school and the range is presented for each group of five schools. The public school of the highest order ($680.45 for scholarships per student enrolled) in this table is an exception that deserves explanation. A legislative appropriation made it possible to extend scholarships with an average value of approximately $1000 to almost two-thirds of the student body and the total scholarship expenditure, if spread over the entire enrollment, would have provided each student with funds more than $100 in excess of tuition costs. This same institution reports no funds available for loan purposes.

Table 43.—*Scholarships Awards "Performance"*
(Dollars Expended per Student Enrolled)

	Public (39)		Private (43)	
Schools	Median	(Range)	Median	(Range)
Upper Five	$122.76	($680.45-76.55)	$213.15	($260.69-203.85)
Middle Five	11.60	(15.95- 9.66)	27.46	(33.86- 24.57)
Lower Five	0	(1.09- 0)	0	(1.91- 0)

In both the publicly and privately owned categories of schools, there are three institutions which by policy grant no scholarships. These six institutions acount for the apparently aberrant figures for the lower five schools.

Forty-four schools reported that all available scholarship funds had been expended and 41 of these same institutions indicate that they could justify the expenditure of considerably greater funds.

Thirty-two schools reported scholarship funds available totaling almost $400,000 that were not utilized. In 24 instances it was indicated that the nonutilization was the result of restrictions imposed by the donor, university policy, or by the committee responsible for administering the funds. Of the 32 schools with unused scholarship funds, 24 state that they could justify the expenditure of additional funds if less restrictive policies governed their use.

Table 44.—*Utilization of Loan Funds, 1957-1958*
(82 United States and 12 Canadian Schools)

	United States Schools		All United States Schools	Canadian Schools
	Public (39)	Private (43)		
Loan funds expended.....	$617,235.00	$680,338.00	$1,292,573.00	$176,614.00
Loan funds expended per student enrolled.....	44.49	45.04	44.77	47.93
Average dollar value per loan.................	354.73	471.47	407.66	238.67
Number of loans granted	1,740	1,443	3,183	740
Per cent of enrollment granted, loans..........	12.5	9.6	10.7	20.1

Fifty schools indicated that first-year students are eligible for scholarship assistance, and in 27 instances eligibility can be established only after completion of the first year.

Gross characteristics of the utilization of scholarship funds by Canadian medical schools are presented in table 42. The major difference between scholarship fund utilization in Canada and the United States is that their funds are spread over a larger portion of the student enrollment. Scholarship dollars expended amounted to 8.3% of the total Canadian tuition charge (in the United States this was 7.0%).

Eleven of the 12 Canadian schools grant scholarships. Two schools reported unexpended scholarship funds of approximately $2,000, and another did not specify the amount unexpended. Seven schools indicated that additional funds for scholarships could be justified.

Eight schools may award scholarships to students at the beginning or in the course of the first year of medical study, and in two schools students are eligible for scholarships only after completing the first year.

Certain gross characteristics of utilization of loan funds are presented in table 44. The significant differences between publicly owned and privately owned medical schools noted in utilization of scholarship funds are not apparent in loan fund utilization. The major difference is that private schools granted loans of greater dollar value to a somewhat smaller percentage of enrolled students.

As was done for scholarship funds, United States medical schools according to type of ownership were arrayed in rank order by expended loan fund dollars distributed over the total student enrollment. Again it is to be emphasized that these data must be considered as representing only an impersonal relationship between loan funds expended and the number of students enrolled during 1957-1958, since this material is presented without specific knowledge of the degree to which real student loan needs were met.

Table 45.—*Loan Granting "Performance" (Dollars Expended per Student Enrolled)*

Schools	Public (39) Median	Public (39) (Range)	Private (43) Median	Private (43) (Range)
Upper five	$115.34	($790.96-73.74)	$126.76	($384.75-108.97)
Middle five	36.21	(38.23-34.60)	29.91	(34.78- 29.18)
Lower five	10.28	(11.94-0)	7.32	(7.99- 1.17)

Table 45 summarized this data; the dollars expended for loans divided by the number of students enrolled are presented for the upper, middle, and lower five schools in the rank order. The figure for the median school and the range is presented for each group of five schools.

The public school of the highest rank order ($790.96 for loans per student enrolled) in table 45 is a two-year institution whose graduates must transfer to medical schools in other states to complete the last two years of medical school study. A few years ago, the state legislature authorized loans up to $2,000 per student per year not to exceed $75,000 in total loans a year for graduates of the granting school while they complete their last two years of study elsewhere. Grantees must be residents of the granting state and must agree to return to that state to practice. Slightly greater sums may be loaned to students who agree to practice in specified small communities in the state; in addition, for each year practiced in such a community, the borrower is forgiven for one-fifth of the loan and interest.

All but one school in the United States and one in Canada granted loans during 1957-1958. Of the 81 United States schools granting student loans (developing schools are not included in this data), 28 utilized all loan funds available, and all but one of these indicated a need for additional funds. In 53 United States schools, loan funds were available that were not completely used. In 21 instances funds were not used in order to maintain a reserve for use in other years or in emergencies; in 15 instances the funds on hand exceeded the student demand; there were 11 schools in which restrictions imposed by donors, university policy, or the committee administering the fund prevented full utilization; in six responses the reason for incomplete utilization was not stated.

About half of the schools in which loan funds were not completely used indicated no need for additional funds for loan purposes. It should be pointed out that probably all schools have established conditions which must be met in order for a student to be eligible to receive a loan. There are, therefore, always some restrictions that govern student loan policies so that responses indicating restrictions as the reason for incomplete utilization of loan funds are in reality dealing with the degree of restriction which manifestly is not assigned a *uniform meaning from one institution* to another. Without uniform standards and policies for both scholarship and loan fund assistance, it is not possible to interpret the degree of student need or the amount of student need that is being met by these funds.

Canadian schools grant smaller, average loans to a greater segment of their student body than do schools in the United States (table 44). Only one Canadian school has no provision for granting student loans and it indicates a need for such a program. Of the remaining 11 schools, 8 did not utilize all loan funds available, and 6 of these state that funds on hand were in excess of expressed student need. One school was unable to use all funds because of restrictions and another because of the need to maintain a revolving reserve. Both of these as well as two of the three schools which had utilized all available loan funds indicated a need for additional sums for student loan purposes.

Forty-three schools in the United States and 7 in Canada may grant loans in the course of the first year of medical school study. Thirty-eight United States and 4 Canadian schools by policy grant loans only after completion of the first year.

Table 46 expresses utilization of scholarship and loan funds as the percentage of tuition charges which funds expended in 1957-1958 could have underwritten. The combined total of scholarship and loan funds for Canadian schools represents a sum equivalent to 17.5% of their tuition charges. In United States schools under public ownership, greater emphasis is placed on student loans as opposed to schools under private ownership in which most emphasis is on scholarships. Perhaps this is to be expected since tuition charges are higher in private schools and scholarship awards would more certainly be directed toward payment of tuition. Although in public schools (United States) grants of scholarships and loans represent a greater percentage (14.4%) of their tuition charges than grants of private schools (11.9%)

Table 46.—*Expended Scholarship and Loan Funds as Percentage of Tuition Charges*

	Scholarship Funds, %	Loan Funds, %	Scholarship and Loan Funds, %
United States Schools			
Public	5.3	9.1	14.4
Private	7.3	4.5	11.9
Total	7.0	6.0	12.8
Canadian Schools	8.5	9.0	17.5

again because of higher tuition charges, the smaller percentage for private schools actually represents a greater absolute sum of money.

STUDENT EMPLOYMENT PRACTICES

To obtain information about outside work done by students for remuneration during the course of medical school studies, schools were queried regarding certain aspects of student employment practices.

Thirty-nine United States schools indicated knowledge of the percentage of each class which engaged in part time employment during the 1957-1958 school year. The school of these 39 that falls in the median position has 7.1% of its first-year class in outside employment. The range of percentage of first-year classes working is from 80% to 0% (in five of the 39 schools, there were no first year students working). The median school for the second year class had 18.5% working with a range of 91% to 0% (three schools in the latter category). The median school for the third-year class had 30% with a range of 90% to 0% (three schools), and for the fourth-year class 40% with a range of 90% to 0% (five schools).

Thirty-nine United States schools reported knowledge of the percentage of students in the second, third, and fourth year classes who were employed (1957-1958) during the school year as externs in hospitals not affiliated with the school for teaching purposes. Ten of these schools reported from 20% to less than 1% of the second year class held positions in nonteaching hospitals as externs during the school year. Twenty-eight of the 39 schools reported that from 34% to 1% of the third-year class were working as externs in nonaffiliated hospitals. Thirty schools of this group reported from 56.5% to 1% of the fourth year class externing in such hospitals during the school year.

From these data it is not possible to estimate accurately the total number of medical students who do part-time work as externs in hospitals not affiliated with medical schools. It seems apparent that there are significant numbers of students, including some in the second-year of medical study, holding such posts. Inevitably these students acquire additional experience in medicine, but, under the circumstances, serious questions can be raised as to whether this experience augments or detracts from the educational efforts of the medical school.

Since the hospitals are not affiliated with medical schools, it can be presumed that for the most part at least this experience is not acquired under the supervision of teachers directly responsible for the students' medical education. It is also possible and perhaps probable that in many instances there may be little if any competent supervision. The same reasons that give cause for concern of exploitation of the student, to the detriment of his sound educational development, also point to a concern that patients given hospital care in such situations cannot have assurance that sufficient judgment and competence are a common basis for all components of the care rendered.

GRADUATES

As was predicted a year ago, the number of graduates in the United States was larger in 1957-1958 than it had been in the previous two years, although it was not as large as the 1954-1955 graduating class, which included as graduates the 50 students completing the intern year required by Stanford University (table 21).

The net increase of 65 graduates in 1957-1958 as compared to 1956-1957 occurred because 38 schools had a total of 274 more graduates, partially offset by 42 schools having 209 fewer graduates, with no change in class size in 5 schools. Twelve schools had a more than 10% increase in number of graduates, the greatest being in schools having recently developed four-year programs such as Mississippi (up 83.4%), Miami (76.5%), and Missouri (52.4%). Other increases occurred also in Albany (22.4%), Buffalo (20%), Medical College of Georgia (19.2%), and Texas Medical Branch at Galveston (up 17.1%). Eleven schools had a decrease of graduates of more than 10%. The largest decreases were in Maryland (down 17%), Utah (15.8%), Baylor (13.3%), Vanderbilt (13.2%), Georgetown (12.1%), and University of Virginia (12%).

Based on the size of the 1957-1958 third-year class, it appears that the graduating class of 1958-1959 will be larger than any prior graduating class except that of 1954-1955. However, the second-year class size in 1957-1958, greatly augmented by the students in the developing schools in 1956-1957 and currently, indicates that a greater increase in number of graduates will occur in 1959-1960. That class will probably set a new record high for number of graduates.

The schools, medical students, and graduates in the Canadian medical schools for the past 10 years appear in table 24. Beginning with the graduating class of 1956-1957, all 12 of the Canadian schools were four-year medical schools. Comparing graduates in the individual schools in the current year and the previous one shows that seven schools had an increased number of graduates in 1957-1958, while five schools showed a smaller number of graduates in 1957-1958, for an over-all decrease of 65 graduates (down 7.2%). Though six schools (Saskatchewan, Dalhousie, Ottawa, Montreal, Alberta, and McGill) had a greater than 10% increase in number of graduates, three schools had a more than 14% decrease (Western Ontario down 33.4%, Queen's down 19.6%, and Toronto down 14.4%). However, based on the size of the third medical year class in 1957-1958, it is anticipated that the number of medical graduates in 1958-1959 will be significantly greater, possibly the largest number of graduates in the past 10 years.

THE NEXT ENTERING CLASS

Based on estimates submitted by the medical schools in the United States, the 1958-1959 entering class may be somewhat larger than was the 1957-1958 class. A total of 11 schools expected an increased number of entering students and 74 schools anticipated no change in their class sizes. No additional schools will enroll students for the first time in 1958-1959. On the other hand, there was a trifle smaller number of applicants in 1957-1958 than there were in 1956-1957 (15,791 as compared to 15,918), indicating that the increased number of applicants in 1956-1957 over the previous year may not have presaged currently a trend toward significantly more applicants over-all.

TABLE 47.—*Foreign Students in Medical Schools in the United States*

Area	Countries, No.	Students, No.
Far East	14	79
Near and Middle East	12	46
Europe	16	66
Latin America		
Caribbean	5	39
Central America	6	24
South America	8	26
North America	1	1
Africa	9	26
Oceania	3	4
Total	75	312

Canadian schools anticipated a slightly smaller entering class in 1958-1959 than in 1957-1958, based on three schools expecting to take fewer entering students while the remaining nine schools expected no change in class size.

INTERNATIONAL EDUCATIONAL EXCHANGE IN MEDICINE

In order to provide an appropriate setting for educational exchange in medicine, the following is quoted[37] from the introductory paragraphs of *Open Doors 1958*, the most recent report on international exchange published by the Institute of International Education.

TABLE 48.—*Foreign Citizens Enrolled in Entering Class of United States Medical Schools*

School Year	Foreign Students in Entering Class, No.
1954-1955	94
1955-1956	97
1956-1957	92
1957-1958	73

> The statistics in *Open Doors 1958*, the report on the five surveys conducted by the Institute of International Education during the academic year 1957-1958, emphasize the growing interest in international educational exchange. Never before have such large numbers of students, faculty members and physicians traveled to and from the United States for educational purposes. There were 52,355 foreign citizens on educational assignments in the United States during 1957-1958; this represents more than a 7% increase over 1956-1957 when 48,560 foreign citizens were reported. Of the 52,355, 43,391 were foreign students; 1,342 were foreign lecturers, professors or researchers who had received appointments to American faculties and 7,622 were foreign interns and residents at United States hospitals. Academic institutions reported 1,689 United States faculty members in teaching or research at the university level abroad. The figures on American students at foreign institutions of higher education cover the 1956-1957 academic year. The results of this survey were delayed because of the time required to receive replies from schools overseas. A total of 12,845 United States students were enrolled in foreign educational institutions in 1956-1957. Primary and secondary school teachers and students are not recorded in *Open Doors.*
>
> The foreign nationals included in Open Doors are citizens of other countries who have come to the United States for educational purposes and who intend to return home upon completion of their assignment. In some cases, however, Hungarian refugee students, whose futures are uncertain, were reported and they have been included. Institute of International Education information indicates that the total number of Hungarian students in residence this year was, however, larger than the 511 reported.
>
> The exchanges represent every major geographical and political area of the world. As in previous years the largest number of exchanges came to the United States from the Far East and the second largest number from Latin America. Thirty-three per cent of all foreign nationals in the United States came from the Far East and 20.9% from Latin America. European, Near and Middle Eastern, and Canadian citizens followed in that order. The new emphasis on academic exchanges with the countries of Eastern Europe has increased the European totals only slightly. Africa and the countries of Oceania are represented again this year by small numbers of exchanges.

TABLE 49.—*United States Citizens Studying Medicine Abroad**

	Total United States Students Abroad	United States Students in Medicine Abroad*
1954-1955	9,457	1,386
1955-1956	9,887	1,863
1956-1957	12,845	(2,000-2,200 ?)

* Excludes United States students studying medicine in Canada.

> The majority of United States citizens abroad—faculty members in 1957-1958 and students in 1956-1957—were located in Europe. The numbers going to Mexico and Canada increased, but as in previous years few Americans pursued their studies in Africa and the Near and Middle East.

The Institute's report indicates that of the more than 43,000 foreign students in the United States (89% of queried institutions responded), most were enrolled in courses in engineering (approximately 10,000) and least in agriculture (approximately 800). Of particular interest are the approximately 750 foreign students enrolled in premedical studies, approximately 1,000 in medicine (undergraduate and graduate but excluding internship and residency) and approximately 1,500 as undergraduate or graduate students in the general field of biological sciences.

FOREIGN SCHOLARS SERVING ON UNITED STATES FACULTIES

There were reported about 1,350 visiting foreign scholars (including professors, instructors, lecturers, and advanced researchers) who served on the faculties of 233 United States colleges and universities during the 1957-1958 academic year. Included in this group were almost 300 foreign scholars serving on United States medical faculties.

FOREIGN STUDENTS (EXCLUDING CANADIANS) ENROLLED IN UNITED STATES MEDICAL SCHOOLS

In 1957-1958 there were a total of 312 foreign students enrolled in United States medical schools (table 47). These students represent 75 different countries and are studying medicine in 65 United States schools. Included in this total of 312 are 73 foreign citizens who were admitted to the entering classes of 33 schools. As is evidenced in table 48 this represents a decrease over recent years.

In addition, 45 foreign students were admitted with advanced standing to the upper classes of 30 United States schools after varying years of medical study abroad. Forty-four of these students were admitted to the second (25) or third (19) year classes, and one was accepted as a senior student. The 45 foreign students admitted with advanced standing and the 73 accepted in the entering class are included in table 47. Canadian citizens are not included in these tables but are considered in the section of this report entitled, "Enrollments and Geographic Source of Entering Students."

A comparison of the number of foreign students in United States medical schools (table 47) with the number of United States citizens studying medicine abroad (table 49) is of interest. These data show from 1,700 to 1,900 more United States citizens enrolled in medical schools abroad than there are foreign citizens enrolled in United States medical schools. From a numerical standpoint, this provides for the United States a favorable balance of positions in medical schools for its students equivalent to four to five additional schools of average United States enrollment. A more qualitative view of this balance is presented in the editorial section of this issue of THE JOURNAL.

TABLE 50.—*Leading Nationality Groups of Foreign Physicians in the United States*

Nationality Group	Physicians, No.

Japan	275
Italy	230
India	225

FOREIGN PHYSICIANS TRAINING IN UNITED STATES HOSPITALS

The Institute of International Education's survey of foreign physicians training in United States hospitals was done in cooperation with this Council. Questionnaires were sent to the 1,405 hospitals approved for internships and/or residencies, with 81.1% of the polled hospitals responding.

According to *Open Doors 1958:*

> During 1957-1958, 7,622 physicians from 90 countries trained in 821 United States hospitals. Of the 7,622, 5,543 trained as resident physicians and 2,079 as interns. The total represents a general increase of 881 physicians over the 6,741 reported last year. This year physicians accounted for 14.5% of the total foreign citizen population surveyed by the Institute of International Education (table 50).
>
> The general increase in the number of foreign physicians was not limited to any particular area. Canada and the countries of Oceania showed a decrease in the number of physicians sent to this country, but an increase was recorded from the Far, Near and Middle East. The greatest increase, one of more than 25%, was shown by Africa.
>
> Of the total number of physicians 1,649 or 21.9% were women. This is an increase of 8.1% over 1956-1957 when only 13.5% were women. Sixty per cent of these women were from the Far East and almost half, 44%, were from the Philippines. As in last year's survey, the Philippines accounted for the largest number of doctors, and approximately half of the doctors sent from the Philippines were women.
>
> Foreign residents were reported in 36 fields of specialization. General surgery attracted the largest number of residents with general medicine, obstetrics, gynecology, pathology, psychiatry, pediatrics, anesthesiology, and internal medicine following in that order.
>
> Foreign physicians were training in 45 states, the District of Columbia, Hawaii, and Puerto Rico. More than 25% of all foreign physicians were located in New York and eight hospitals reported more than 50 foreign doctors (table 51).

UNITED STATES FACULTY MEMBERS ABROAD

During the 1957-1958 academic year, approximately 1,700 faculty members from some 350 United States colleges and universities accepted teaching and/or research assignments in other countries. Of this group, about 100 were members of medical faculties.

UNITED STATES STUDENTS STUDYING MEDICINE ABROAD

In previous reports, the Institute of International Education has collected data on the total number of United States students studying abroad and also the numbers by major fields of study. These data have always been for the academic year preceding the year of the report. *Open Doors 1958* presents the total number of United States students studying but does not break that down into major fields of study. However, by interpolating from previous Institute of International Education data, it can be estimated that in the academic year 1956-1957 there were in the range of 2,000 to 2,200 United States citizens enrolled in medical schools outside the United States and Canada (table 49).

As has been noted previously in the annual reports on medical education, the large number of United States citizens enrolled in medical schools outside the United States and Canada must be viewed with serious concern. During the three academic years covered in table 48, the ratio of applicants to admissions in United States schools has been in the range of about 2:1. Under these circumstances, it appears likely that many of the increasing number of American students now studying medicine abroad were not considered qualified for such study in United States schools.

It has been possible for the past several years to collect information regarding the numbers of American-born graduates of medical schools outside the United States and Canada who have received their initial medical licenses in the United States. This is presented in table 52. It is to be noted that the increase of more than 100 such licenses issued in 1957 over 1956 is almost entirely accounted for by New York. Of the total initial licenses issued in 1957 to American-born graduates of foreign medical schools, 70% were granted by the state of New York.

Table 52.—*Initial United States Licenses Issued to American Graduates of Foreign (Excluding Canada) Medical Schools*

Year(s)	Licenses Issued, No.	States, No.
1950-1954	99	20
1955	89	19
1956*	103	15
1957*	212	17

* Includes number of licenses issued by New York (1956—50 and 1957—151) and Pennsylvania (1956—0 and 1957—9) which were not available in other years.

It probably is of equal or even greater pertinence to know how many American-born graduates of foreign medical schools failed initial state board examinations. It is hoped that such information can be collected for presentation in next year's report.

THE EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES

This new organization whose program has been presented previously[38] went into active operation in October, 1957. The initial evaluation of a group of foreign trained physicians took place in the United States in March, 1958. Of 298 graduates of foreign medical schools whose medical credentials were found adequate, 51% (152) demonstrated satisfactory knowledge of medicine and English and were certified to this effect by the Educational Council for Foreign Medical Graduates.

Another examination of knowledge in medicine and English was conducted early this fall both in the United States and in approximately 30 testing centers abroad.

Several state licensing boards and several specialty boards have already indicated that they will require graduates of foreign medical schools to be certified by the Educational Council for Foreign Medical Graduates as a prerequisite to examination for licensure or specialty certification.

The Council on Medical Education and Hospitals, in collaboration with the Executive Council of the Association of American Medical Colleges, has prepared and circulated widely in the United States and other countries a statement indicating their support of the Educational Council for Foreign Medical Graduates. These two groups state their intention to withdraw by Jan. 1, 1960, the listing of certain foreign medical schools whose graduates have been recommended for consideration on a basis comparable to that of graduates of our own approved schools.

In place of this listing, the Council on Medical Education and Hospitals and the Association of American Medical Colleges recommend that licensing boards, hospitals, specialty groups, and other organizations in the United States concerned with the medical qualifications of graduates of foreign medical schools, consider certification by the Educational Council for Foreign Medical Graduates as evidence that the recipient of such certification is possessed of medical knowledge comparable to that expected of graduates of approved medical schools in the United States and Canada. In the interval before the Jan. 1, 1960, effective date of withdrawal of the listing of certain foreign medical schools, the Councils concerned will support the recommendations in regard to graduates of the listed schools and also the recommendation pertaining to certification by the Educational Council for Foreign Medical Graduates.

The Council on Medical Education and Hospitals has revised its *Essentials of Approved Internships and Essentials of Approved Residencies and Fellowships* to indicate that hospitals considering foreign medical school graduates for internship or residency positions are recommended to acquire reasonable assurance regarding the medical qualifications of foreign trained physicians by deferring their appointment until the candidates have been certified by the Educational Council for Foreign Medical Graduates. The American Hospital Association has supported this recommendation through appropriate notification of its member hospitals. It is expected that all graduates of foreign medical schools serving as interns or residents in United States hospitals as of July 1, 1960, will have been certified by the Educational Council for Foreign Medical Graduates.

POSTGRADUATE MEDICAL EDUCATION

A detailed study was not undertaken for the 1957-1958 year of enrollments in postgraduate courses for the continuation education of physicians or of the categories and numbers of courses and the methods of education. A fairly definitive analysis of those activities based on information collected in the year beginning Sept. 1, 1956, was presented in the 57th annual report [30] a year ago. It was felt that no useful purpose would be served by collecting and analyzing similar data for the current year. Further, the information secured from the organizations and institutions sponsoring postgraduate courses in 1956-1957 is still under study, particularly those items concerned with the geographical residence of the physicians enrolled in courses as compared to the locations of the courses offered and their subjects. Already a singular and unexpected mobility of many physicians who travel considerable distances to postgraduate courses has appeared as a significant factor. It is anticipated that the geographical study, which will be published in the next year, should provide information useful to those sponsoring postgraduate courses and related programs.

The annual list, Postgraduate Courses for Physicians, for the calendar year beginning Sept. 1, 1958, was published in The Journal, Aug. 16, 1958.[39]

EDUCATIONAL VALUES OF THE GRANTS AND TRAINING AWARDS PROGRAMS OF THE UNITED STATES PUBLIC HEALTH SERVICE

Because of their rapid growth since 1945 and their contribution and impact on undergraduate medical education, graduate education and training, and on the research activities and potentials of medical schools, any current report on Medical Education in the United States would be incomplete without presentation of the Educational Values of the Grants and Training Awards Programs of the United States Public Health Service. The following information reviewing the current status of these programs was prepared and submitted by the Office of Research Information, National Institutes of Health, Public Health Service, United States Department of Health, Education, and Welfare.

The United States Public Health Service conducts three types of programs that contribute significantly to America's supply of personnel in the medical and biological sciences. Directly concerned with research manpower are the programs that provide training grants and fellowships to nonfederal institutions and scientists. These awards will aid approximately 6,000 persons in 340 schools in 1958. Of greater magnitude, but offering educational values only indirectly, are the programs of grants for research and research construction. Lastly, there are the various intramural training programs in the Service's research centers and 72 hospitals. All these activities have grown rapidly since World War II. They have greatly increased the research and training potential of schools, have fostered activity in needed areas of investigation, and have advanced the search for basic causes of disease. They have helped expand medical knowledge and the body of professional workers skilled in its application.

The National Institutes of Health, Public Health Service research center at Bethesda, Md., spends more than two-thirds of its annual appropriations for support of nonfederal research projects and research training. The importance of National Institutes of Health to the nation's science structure and medical progress is reflected in the postwar appropriations made by Congress for research fellowships, training awards, and research grants (table 53).

A wide range of medical and biological investigations is conducted and supported by the seven institutes—the National Cancer Institute, National Heart Institute, National Institute of Allergy and Infectious Diseases, National Institute of Arthritis and Metabolic Diseases, National Institute of Dental Research, National Institute of Mental Health, and the National Institute of Neurological Diseases and Blindness. In addition to these institutes, five divisions of the Public Health Service share in the responsibility for research project and training awards. One of these, the Division of Research Grants, coordinates the grants and training programs of the institutes and administers awards programs not falling within the seven disease categories.

Table 53.—*National Institutes of Health Appropriations for Grants and Awards to Nonfederal Institutions, Agencies, and Individuals for Fiscal Years 1945, 1950, and 1955-1958*

Year	Research Fellowships	Training Awards	Research Grants
1945	$ 28,000	$ 29,000	$ 85,030
1950	1,448,057	6,415,060	13,065,514
1955	2,562,000	11,051,000	33,918,000
1956	2,800,000	14,502,000	38,038,000
1957	5,397,000	28,075,000	89,697,000
1958	6,812,000	32,560,000	90,345,000

Nine national advisory councils, composed of nonfederal leaders in medical science and public affairs, review all grant applications within their respective program areas and recommend action to the surgeon general. They are assisted by 28 study sections—panels of outstanding specialists, mostly nonfederal, who are selected by the Division of Research Grants. In addition to these specific functions, the councils and study sections, as well as various special committees, contribute over-all policy guidance in the research grant and training activities.

Below are brief descriptions of the Public Health Service programs that offer educational values. (Further information may be obtained from the Division of Research Grants, National Institutes of Health, Bethesda 14, Maryland.)

Research Fellowships

Six classes of research fellowships are available from the National Institutes of Health to qualified United States citizens (or persons who have filed a *Declaration of Intent*). Predoctoral, postdoctoral, and special research fellowships are awarded to individual applicants. Senior research fellowships and student part-time research fellowships are available through schools of medicine, dentistry, nursing, and public health. Post-sophomore research fellowships are available through schools of medicine and dentistry. Applications are processed by the Division of Research Grants, and the awards are made on a competitive basis upon recommendation by scientific committees.

The predoctoral research fellowship enables students with a bachelor's degree, master's degree, or equivalent training to pursue graduate research in the health sciences. Predoctoral fellowships are awarded for one year with assurance of support to the degree status if work continues to be satisfactory. Annual stipends for the first, second, and third years are $1,600, $1,800, and $2,000 respectively. The fellowship provides tuition, allowances of $350 for dependents, and certain travel expenses.

The postdoctoral research fellowship is awarded to candidates having an M.D., Ph.D., D.D.S., or equivalent degree. It carries a stipend of $3,800 for the first year, $4,200 for the intermediate year, and $4,600 for the third year. Dependency allowances are the same as for the predoctoral research fellowship. This year, for the first time, several postdoctoral fellowships were awarded to European scientists, enabling them to train at American medical research centers of their choice. This extension of the program is intended to promote exchange of ideas and knowledge.

Special research fellowships are awarded to qualified applicants with unusual competence in research or specialized research training. The stipend for each fellowship is determined at the time of award.

Senior research fellowships encourage highly competent scientists to conduct research in the preclinical sciences—anatomy, physiology, biochemistry, microbiology, pharmacology, pathology, biophysics, genetics, and the behavioral sciences. This program provides support between the completion of postdoctoral training and the time of eligibility for appointment to higher academic posts. Applicants must be sponsored by a basic science department of an accredited medical school, dental school, or school of public health. The fellowship provides a salary determined by the sponsoring institution. Partial research expenses up to $2,000 a year are also financed. Fellows are free to modify their research approach, to obtain additional support from the Public Health Service or other sources to conduct a portion of their research in other institutions, and to assume teaching responsibilities conducive to their academic development.

Student part-time research fellowships are designed to permit students to explore the field of research. Medical schools may request up to eight part-time fellowships in units of $600 each. Dental schools may request up to six units; schools of nursing and of public health up to four. Each unit provides for part-time research during the school term or for full-time research during two months of any period when curriculum work is not scheduled for the student.

A new type of award, the postsophomore research fellowship, was instituted in 1957. It enables medical and dental schools to help students interested in research careers to obtain essential training in the basic sciences. Participants drop out of regular course work during the training period. They receive full tuition, dependency allowances, and a stipend set by the school not to exceed $3,200.

Visiting Scientist Program

The visiting scientist program is a flexible arrangement for inviting outstanding American and foreign scientists to utilize the extensive laboratory and clinical research resources of the National Institutes of Health. Two classes of appointment are available—"visiting scientist" and "research associate in the visiting scientist program." Participants must have a doctoral degree or the equivalent background, at least six years of postgraduate experience, and exceptional ability in a specific research problem. The salary range is from $5,400 to $12,600 a year. The purpose of the program is to increase the utility of the National Institutes of Health as a national resource and to strengthen interrelations with the broader scientific community.

Training Grants

The training grants program of National Institutes of Health is intended to augment the nation's supply of qualified scientific investigators by assisting in the establishment, expansion, and improvement of training and instructional programs in professional institutions. Training grants are made to schools of medicine, dentistry, nursing, and public health. Direct aid to the institution is provided by grants in two general classes—undergraduate and graduate.

Undergraduate training grants are awarded by the National Cancer Institute, National Heart Institute, and National Institute of Mental Health. The specific purpose of this program is to establish, continue, expand, or improve instruction relating to the prevention, diagnosis, and treatment of cancer, mental illness, and cardiovascular disease or related gerontological conditions.

Graduate training grants are awarded by all seven of the institutes. The objective is to assist professional schools in establishing and maintaining graduate instructional and training programs of high caliber as well as to make funds available for the payment of trainee stipends.

Mental health career investigator grants, awarded by the National Institute of Mental Health, provide psychiatrists and scientists in related disciplines with an opportunity to acquire three to five years of full-time research training in mental health. The applicant institution, which may be a psychiatric research institution or a department of psychiatry in a medical school, pays the trainee a stipend ranging from $6,000 to $10,000 a year.

Two additional training grant programs were recently established by the National Institutes of Health—an experimental program for training undergraduate medical students in research methodology and a program of a graduate training grants in epidemiology and biometry. Both programs are administered by the Division of Research Grants. The experimental training program offers special grants to universities seeking to improve methods for training medical students for research careers. The funds paid to applicant schools include salaries of professional and nonprofessional personnel and stipends for individuals in training.

Traineeships

Traineeship awards are intended to increase the number of investigators by encouraging advanced training in specialized areas of medical research. Examples of interest are the neurological diseases, ophthalmology and sensory diseases, diagnosis and treatment of cancer, and arthritis, diabetes, and other metabolic diseases.

Regular or special traineeships are awarded directly to American citizens having a doctoral degree in health fields, including related biological and behavioral sciences. Traineeships are available through the National Cancer Institute, the National Institute of Arthritis and Metabolic Diseases, and the National Institute of Neurological Diseases and Blindness. The National Heart Institute and the National Institute of Mental Health provide traineeships under training grants awarded to institutions for this purpose.

The regular traineeship carries a first-year stipend of $3,800, a second-year of $4,200, and a third-year of $4,600, plus dependency allowances of $350 and certain travel allowances. No allowances are made for tuition or supplies.

Special traineeships are awarded in varying amounts to qualified individuals who possess unusual competence for training or who require specialized training for a specific problem. The trainee may study at the institution of his choice. The stipend is determined by the particular training needs of the applicant. The National Institute of Neurological Diseases and Blindness awards special traineeships only to those who have completed residency requirements in a specialty.

Recent amendments to the Public Health Service Act provide traineeships for professional health personnel, supplementing the training activities of state and local governments. The program is administered by the Division of General Health Services, Bureau of State Services. Its primary purpose is to bring new people into the field of public health—physicians, dentists, nurses, and other professional health workers who have completed their basic education. Preference is given to applicants under 35 who have had no more than two years experience in public health work and have had less than a year of graduate or specialized training in public health. Consisting of stipends, tuition, and certain allowances, the awards are paid directly to participants, with the exception of those made available through schools of nursing and of public health. Stipends range from $2,400 to $4,800, according to the applicant's academic degree.

Another amendment to the Public Health Service Act provides traineeships to prepare nurses for teaching, supervision, and administration in all fields of nursing including public health. Stipends of $2,400 to $3,600 plus tuition, certain travel fees, and dependency allowances of $360 are available through schools of nursing. This program is administered by the Division of Nursing Resources, Bureau of Medical Services.

Research Grants

Research grants support medical research on all major health problems and in basic sciences related to medicine. Each institute makes grants for research within its area of interest, and the Division of Research Grants supports studies outside the scope of the seven institutes. The program is intended to increase research in medical, dental, and other professional schools and institutions and to stimulate investigations in scientific areas needing exploration. A sizable portion of the grants is devoted to basic research. The program aids indirectly in training junior personnel employed in the research projects.

The research grants constitute by far the largest program of Public Health Service awards, both in terms of money expended and the number of institutions affected. Appropriations supported approximately 6,000 such grants in 1957.

Field investigation grants, awarded by the National Cancer Institute, support developmental research, community studies, and surveys that will contribute to the prevention, control, diagnosis, and treatment of cancer in the general population.

The National Institutes of Health cooperate with the two service bureaus of the Public Health Service in administering grants for special research projects. Among these are investigations of the health aspects of air and water pollution, projects for the development and utilization of hospital facilities and resources, and studies to improve nursing education and service. The projects are administered by the Division of Research Grants for the sponsoring divisions in the Bureau of State Services (the Division of Sanitary Engineering Services and the Division of General Health Services) and in the Bureau of Medical Services (the Division of Hospital and Medical Facilities and the Division of Nursing Resources).

Health Research Facilities

In 1956 Congress approved a three-year program of construction grants to accelerate the building and equipping of urgently needed new laboratories and other health research facilities. Thirty million dollars was appropriated and granted in fiscal year 1957; another 30 million dollars has been appropriated for 1958; and present authorization includes 30 million dollars for one additional year. Applications submitted by nonfederal public and private institutions to the Division of Research Grants are evaluated by the National Advisory Council on Health Research Facilities, which in turn recommends action to the surgeon general. The construction projects are financed on a matching basis.

Training for Public Health Service Careers

The Public Health Service, in its widespread and diversified programs, offers many career opportunities to competent physicians. Training is provided in various areas of medicine, including patient care, clinical research, basic laboratory research, epidemiology, preventive medicine, quarantine duty, foreign service, and public health administration.

Most of the Service's physicians are officers in the Commissioned Corps, which has served this country with distinction since 1873. A young physician or medical student may enter the Corps (1) through the Commissioned Officer Student Training and Extern Program (COSTEP), (2) as an intern upon graduation from medical school, and (3) as a medical officer after non-Service internship.

Clinical assignments are available in most of the Service's 16 general and special hospitals and in many of its 56 hospitals for American Indians and Alaskan natives. Postgraduate medical education in the teaching hospitals is conducted by chiefs of service (who are certified or eligible for certification by their specialty boards), with the assistance of well-qualified personnel and outstanding consultants from local hospitals and medical schools. Approved internships are also offered in dentistry, dietetics, and pharmacy.

Rotating internships consisting of assignments planned to round out a young physician's education are available in the Service's hospitals at Baltimore, New Orleans, New York, Norfolk, San Francisco, Seattle, and Boston. The schedule provides four months of medicine, four of surgery, two of pediatrics, and two of obstetrics. Mixed internships, available at the Public Health Service hospital in Boston, provide six months of medicine and six of surgery.

In addition to the usual educational requirements, the applicant for appointment as a medical intern must (1) be in good health, (2) be an American citizen, and (3) submit an application for a reserve commission in Public Health Service. Those who have satisfactorily completed the year's internship may apply for continuing assignment with the Service. They are eligible to take the examination for appointment in the Regular Corps.

In addition to internships, Public Health Service hospitals offer approved residency training in the following specialties: surgery, general practice, internal medicine, orthopedics, urology, anesthesiology, dermatology and syphilology, ophthalmology and otolaryngology, pathology, radiology, and psychiatry. The National Institutes of Health Clinical Center, 500-bed research hospital at Bethesda, Md., offers residency training in internal medicine, neurology, ophthalmology, pathology, psychiatry, and radiology. Residents are usually selected from the Commissioned Corps.

Through the Commissioned Officer Residency Deferment (CORD) program, Public Health Service offers qualified physicians the opportunity to obtain deferment from military service under the Universal Military Training and Service Act. Physicians are commissioned in the Reserve Corps of Public Health Service and deferred from active duty to obtain residency training in essential specialty fields. After completion of training, participants must serve their obligatory time with Public Health Service. No additional military service is required.

The program known as COSTEP provides employment for a limited number of medical and dental students during the vacation months for duty at Public Health Service hospitals, research laboratories, and other facilities. Appointments are offered to students who will have completed their sophomore year of professional education by July 1 and are interested in becoming reserve officers in the Commissioned Corps.

Inquiries concerning employment in the Public Health Service may be obtained from the Surgeon General, United States Public Health Service (P), Washington 25, D. C.

Conferences and Seminars

To encourage early and adequate exchange of information among investigators, numerous conferences, seminars, and symposiums are supported in connection with the grants and training programs. Many of the meetings are initiated and sponsored by the advisory study sections of the Division of Research Grants.

In addition, the institutes, separately or as a whole, present lectures, seminars, and clinical conferences. Frequently there is active participation by faculty members of universities and medical schools, staffs of other research centers and Public Health Service hospitals, physicians in private practice, and other leaders in the medical sciences.

Research workers met at a conference held in 1957 under the auspices of the Surgery Study Section to discuss developmental, technical, and clinical problems in extracorporeal circulation. The Sensory Diseases Study Section, in hopes of stimulating interest among young investigators, assembled experts in retinal physiology, biochemistry, optical physics, and psychology to discuss the present status of knowledge of visual mechanisms within the eye and brain.

The Radiation Study Section sponsored a series of conferences in 1957 and 1958 to facilitate the application of radiobiological knowledge to the treatment of cancer. Work conferences on research training for nurses and on special clinical training in cardiovascular nursing were inaugurated by the Nursing Research Study Section in 1958. The Biophysics and Biophysical Chemistry Study Section sponsored regional conferences in 1956 and 1957 to help determine how best to provide training and develop research in the theory and practice of medical-science instrumentation, and in 1958 the Section held two conferences to explore research and training opportunities for scientists and mathematicians in the new field of physical biology.

A postgraduate course on research in cardiovascular disease was given by National Institutes of Health for the American College of Physicians in the fall of 1957, and other courses for the College are planned. Meetings such as those supported by the National Institute of Mental Health provide orientation and training in specific services—the annual conferences, for example, on the reporting of mental hospital statistics. The National Institutes of Health also provides personnel and exhibits for medical and scientific meetings of state, regional, national, and international scope.

THE NATIONAL SCIENCE FOUNDATION

The following résumé of the activities of the National Science Foundation, in so far as they are related to medicine through grants for basic research in the medical sciences, grants for short-term medical research, and fellowships for study at the graduate and postdoctoral level, has been submitted by the Public Information Office of the Foundation.

The National Science Foundation, an agency of the federal government, was established by Congress in 1950 "to promote the progress of science; to advance the national health, prosperity, and welfare; to secure the national defense; and for other purposes." The foundation carries out its mission by supporting basic research in the sciences, programs for improving science education, conferences and symposia on specific aspects of science, studies of manpower supply and demand, programs for making scientific information more readily available, and the compilation of data on the national effort in scientific research and development.

Of particular interest to the medical profession are the foundation's grants for basic research in the medical sciences, grants for short-term medical research, and fellowships for study at the graduate and postdoctoral level (table 54).

Basic Research

Grants are made to help competent scientists conduct basic research in the sciences, principally at universities and colleges. Normally, proposals are originated by the scientist and are endorsed and submitted by his institution. Basic Research is supported in the mathematical, physical, medical, biological, engineering and other sciences, including to a limited extent, the social sciences. In 1957, the Congressional appropriation to the foundation for the support of basic research was $15,500,000. Approximately $7,360,000 was expended in support of the life sciences. In 1958, the appropriation for the support of basic research was $19,400,000, with approximately $8,000,000 for the life sciences.

TABLE 54.—*NSF Support of Activities (Research and Conferences) of Interest to Medical Profession*

	Fiscal Year 1957		Fiscal Year 1958	
	Number	Amount	Number	Amount
Basic medical research grants....	22	$407,200	24	$559,600
Short-term research by medical students..............	16	194,400	17	193,200
Conferences and symposia on subjects of medical interest.....	3	18,000	1	20,000

Short-Term Medical Research

In an effort to increase the number of scientists qualified to perform basic research in medical fields, the foundation sponsors a program designed to encourage medical school students to pursue careers in research.

Medical school students constitute one of the largest sources, relatively untapped, of medical research scientists. The medical curriculum is essentially instructional, offering little, if any, opportunity for students to pursue research and become familiar with its methods or challenges. The foundation seeks to introduce medical students to the techniques of basic research by means of its grants to medical schools for the support of short-term research by students during free-quarter periods. Without interfering with the medical curriculum, the program provides opportunities for carefully selected students to determine their interest in and aptitude for research. Student research is conducted under the supervision of qualified members of the medical school staff.

In 1956, the foundation began this program experimentally. In the three years of its operation, the program has expanded considerably and now includes 34 medical schools in the nation. A total of $467,250 has been granted for this purpose.

Conferences and Symposia

The conferences and symposia supported by the foundation provide excellent opportunity for the interchange of information and ideas among experienced investigators, as well as an opportunity for younger investigators to meet and obtain information and advice from some of the world's foremost scientists. Approximately 25 such conferences are supported each year. In 1957 there were three such conferences of special interest to those in the medical profession and in 1958, one (table 54).

Additional information on the support of research grants in the medical sciences may be obtained from the Division of Biological and Medical Sciences, National Science Foundation, Washington 25, D. C.

Fellowships

The Fellowship Program of the foundation is designed to strengthen the nation's potential by providing support for advanced training in the sciences directed toward the development of highly qualified research scientists and for further study in the sciences directed toward increasing the competence of college science teachers.

Fellowships are offered for graduate study in the physical, medical, biological, and engineering sciences; anthropology and psychology (excluding clinical); and geography, certain interdisciplinary fields, and selected social science fields. These fellowships are limited by law to citizens of the United States. A Fellow may study under his award at any accredited nonprofit institution of higher education in the United States or any similar institution abroad approved by the National Science Foundation.

Awards are *not* made to individuals to pursue a course of study designed to prepare them for careers in medical practice or other clinical fields; applications are accepted, however, from students who intend to obtain advanced training in one of the medical sciences directed toward a career in research. An individual who holds a degree such as M.D., D.D.S., or D.V.M. and desires to continue training for a career in research is eligible to apply for a postdoctoral award provided he can present an acceptable plan for study and research.

Four types of fellowships are offered—the Predoctoral, Regular Postdoctoral, Senior Postdoctoral and Science Faculty. The predoctoral program is open to students studying for masters or doctoral degrees in science. The three predoctoral levels, first-year, intermediate-year, and terminal year, carry base stipends of $1,600, $1,800, and $2,000, respectively, with allowances for travel and dependents. Approximately 1,000 predoctoral fellowships were awarded during 1958.

The regular postdoctoral program is available to those who have earned a doctoral degree or have had research training and experience equivalent to that represented by such a degree. The stipend is $3,800 with allowances for travel and dependents. These awards are made semiannually, and approximately 125 were made in 1958.

The objective of the senior postdoctoral program is to provide senior, established scientists an opportunity to increase their competence as investigators in their own or related fields. These scientists should have held their doctoral degree for a minimum of five years. A salary-matching stipend is awarded, up to a maximum of $12,000. Approximately 75 such fellowships are awarded each year.

To increase the effectiveness of the teaching of college science teachers, the foundation awards annually science faculty fellowships to teachers with three years college teaching experience and plan to continue teaching. A salary-matching stipend is given, up to a maximum of $12,000. Approximately 180 such fellowships were awarded in 1958.

During fiscal year 1957, 34 fellowships were awarded in the medical sciences. There were 20 predoctoral, 9 regular postdoctoral, 2 senior postdoctoral, and 3 science faculty fellowships. During fiscal year 1958, 41 fellowships were awarded in the medical sciences—15 predoctoral, 18 regular postdoctoral, 5 senior postdoctoral, and 2 science faculty.

Additional information on the Predoctoral and Regular Postdoctoral Fellowship Programs of the National Science Foundation may be obtained from the Fellowship Office, National Academy of Science-National Research Council, Washington 25, D. C.

Additional information on the Senior Postdoctoral and Science Faculty Fellowship Programs may be obtained from the Division of Scientific Personnel and Education, National Science Foundation, Washington 25, D. C.

CONTRIBUTIONS OF THE OFFICE OF VOCATIONAL REHABILITATION TO MEDICAL EDUCATION AND RESEARCH

Since 1954 the Office of Vocational Rehabilitation, under authority of the Vocational Rehabilitation Act, has offered direct and indirect aid of five types to medical education and research. The following summary of the various grant programs administered by the Office of Vocational Rehabilitation which have an impact on medical education has been prepared by its administrative staff for the education number of THE JOURNAL.

The Office of Vocational Rehabilitation, Department of Health, Education, and Welfare, offers direct and indirect aid to medical education. Direct aid is available in the form of long-term teaching grants and short-term course or institute grants to the schools. Less direct but significant support is provided through research grants, research fellowships, and traineeships. These five types of aid, made possible under authority of the Vocational Rehabilitation Act of 1954, may be summarized as follows:

1. Teaching grants for long-term training assist the schools in initiating, expanding, or improving teaching in the rehabilitation phases of medicine. The number of medical schools receiving teaching grants has increased from 6 in 1956 to 25 during the current academic year. Averaging from $15,000 to $25,000, the grants are intended to provide part of the costs of the teaching program. Generally, they cover the salary of a faculty member coordinating the program, payment for the part-time services of supporting staff, and the purchase of instructional equipment or materials. The duration of these grants is one academic year with provision for reapplication by the institution for continued support.

2. Short-term course grants are made to medical institutions to stimulate interest and to increase knowledge regarding the potentialities of rehabilitation. Funds from this source may also be used to pay part of the costs incurred by those in attendance. During the past year, specialized courses were conducted in geriatric rehabilitation, the teaching of esophageal speech, and administrative problems encumbered by physicians engaged as medical consultants in the state-federal vocational rehabilitation program. Short-term courses dealing with prosthetic rehabilitation of the upper extremity amputee and the above-knee amputee reached in 1957 an estimated 600 physicians, physical therapists, occupational therapists, and prosthetists.

3. Traineeship grants in medicine serve the purpose of increasing the nation's supply of qualified physiatrists. They were given during the past academic year, to 25 institutions offering approved residency programs in physical medicine. From this source the institutions, in turn, awarded traineeships to individual physicians. The number of physicians receiving this type of support has increased from 4 in 1955 to 139 during the past academic year. Expenditures for such traineeships, which averaged $6,000 per trainee, increased from $287,500 in 1956 to $650,000 in 1958.

Office of Vocational Rehabilitation funds have also been used in several institutions to establish part-time courses in rehabilitation methods and concepts for graduate physicians engaged in residencies in neurology, neurosurgery, orthopedics, psychiatry, urology, plastic surgery, etc.

4. Research and demonstration grants are available for the partial support of projects aimed at developing more effective methods and techniques for the vocational rehabilitation of the more severely disabled. Although no specific matching is required, sponsors of current active projects are carrying an average of 33% of the total cost of the projects. Research and demonstration grants are recommended for approval by the National Advisory Council on Vocational Rehabilitation which is composed of medical, educational, and scientific members who are established authorities in fields concerned with vocational rehabilitation.

Projects are being encouraged in the following categories: (*a*) studies designed to determine physiological changes which occur during treatment and retraining in physical rehabilitation; (*b*) the development of new and improved diagnostic techniques; (*c*) investigations to elucidate the dynamics of individual and group motivation as a factor in success or failure of physical medicine procedures; and (*d*) projects for developing quantitative methods for evaluating functional capacities of disabled individuals.

5. Research fellowships may be awarded to assist qualified candidates to pursue advanced training for research in rehabilitation or to undertake a research project which holds promise of advancing knowledge of the vocational rehabilitation of disabled persons. Three types of fellowship are available: predoctoral, postdoctoral, and special. The awards are made on an annual basis and are subject to a limitation of two years.

The programs of the Office of Vocational Rehabilitation in aid to medical education are based on long-standing practices of cooperation with state and local agencies and medical institutions. National advisory committees play a major role in the administration of the office's educational grants program. These committees, composed of leaders in the educational, research, and administrative phases of the various rehabilitation disciplines, have helped to formulate the policies and basic principles which govern the grant programs for medical education. Academic freedom for the institutions and individuals receiving grants is a primary consideration. The intent of Congress, the recommendations, of the advisory committees, and the traditions and experience of the Office of Vocational Rehabilitation provide maximum safeguards for that freedom. In carrying out the over-all program, every effort is made to insure the widest distribution of funds, taking into consideration the number and quality of the projects and the available resources.

UNDERGRADUATE AND GRADUATE MEDICAL TRAINING PROGRAMS IN THE VETERANS ADMINISTRATION

The following material reviewing the Undergraduate and Graduate Medical Training Programs in the Veterans Administration has been submitted by the Director, Education Service, Research and Education, Department of Medicine and Surgery of the Veterans Administration.

The Veterans Administration medical school relationship which resulted from the 1946 congressional action organizing a Department of Medicine and Surgery within the Veterans Administration had as its principal purpose the organization and supervision of graduate training programs in Veterans Administration hospitals by medical school faculties. This relationship was formalized by a policy memorandum issued Jan. 30, 1946, and at that time undergraduate medical education was not considered in establishing the Veterans Administration medical school relationship.

On Nov. 21, 1957, nearly 12 years after the inauguration of this relationship, a letter survey was made of all Veterans Administration hospital managers and all deans of associated medical schools asking for a reevaluation of the Veterans Administration medical school relationship. The results of this survey will be reported in another publication at a future date, but the significant feature of the replies was a unanimous endorsement and recommendation for continuing the relationship. This relationship has endured for 12 years because it is mutually beneficial to both the medical schools and the veterans hospital.

TABLE 55.—*Veterans Administration Residents, April, 1958*

	Career Residents	All Other Residents	Total Residents
Allergy	0	4	4
Anesthesiology	11	67	78
Cardiology	0	8	8
Dermatology	0	30	30
Gastroenterology	0	5	5
General surgery	0	696	696
Internal medicine	0	644	644
Neurology	17	18	35
Neurosurgery	0	34	34
Ophthalmology	0	63	63
Orthopedic surgery	0	111	111
Otolaryngology	0	29	29
Pathology	7	82	89
Physical medicine	23	7	30
Plastic surgery	0	11	11
Psychiatry	184	186	370
Pulmonary diseases	0	13	13
Radiology	20	133	153
Thoracic surgery	0	26	26
Urology	0	86	86
Totals	262	2,253	2,515

UNDERGRADUATE MEDICAL EDUCATION

For the academic year 1957-1958, 62 medical schools assigned 6,022 medical students to Veterans Administration hospitals of which 4,917 (82%) were third and fourth year clinical clerks. Many others assigned students on other than clerkship basis. Eighteen Veterans Administration hospitals received 100% of the third year medical school class and 16 hospitals received 100% of the fourth year medical school class for clerkship training.

GRADUATE TRAINING PROGRAMS

Table 55 indicates that residency training is conducted in 20 medical specialties in Veterans Administration hospitals. As of April 15, 1958, there were 2,515 residents on duty of which 262 were "career residents" receiving the pay of full-time physicians in return for a contractual obligation to serve specified periods of obligated service at the conclusion of their formal residency training.

While all authorized residency positions are filled, the facilities of Veterans Administration hospitals would permit significantly greater numbers of residents to be trained provided both funds and resident candidates were available. The actual capacity of Veterans Administration hospitals engaged in residency training is 3,806, although this number of positions has never been offered at any time.

The 2,515 residents on duty in Veterans Administration hospitals represent 82% of all reported residency appointments in the federal services and represents 11% of all residency appointments throughout the United States.

Veterans Administration hospitals participate in 626 different individual residency programs. Of these, 29% are conducted as integrated programs by combination with university programs in the community. They are, therefore, not independently approved and are usually listed in THE JOURNAL of the American Medical Association under an "indented" heading. Three hundred and eight (49%) are independently approved in the name of the Veterans Administration but are conducted in collaboration with other approved programs. Sixty-two (10%) are conducted on an affiliate basis with approval for such programs resting in the name of another hospital than the Veterans Administration. Forty-seven (7%) are independently approved and conducted without any outside collaboration or affiliation, while 42 (5%) of the programs are now pending approval.

FOREIGN MEDICAL SCHOOL GRADUATES

During the past fiscal year, 168 residents were graduates of foreign medical schools, and 16 of the total were graduates of Canadian medical schools. In addition to the above United States citizens who were graduates of foreign schools, 89 noncitizen residents were serving on a "without compensation" basis by assignment from university hospitals. Twenty-six noncitizens were assigned with Veterans Administration hospitals having residency training programs on a "guest student" basis to act as observers only and not to participate in residency training programs from the standpoint of assuming responsibility for patient care.

Recognition of the approved status of Canadian medical schools finds expression in a relaxation of the previous requirements for citizenship. At present, a noncitizen who is a graduate of an approved Canadian or American medical school may be employed as a resident in Veterans Administration hospitals. United States citizens who are graduates of other foreign medical schools may not be employed unless holding certification from the Educational Council on Foreign Medical Graduates, Inc.

RESIDENT COMPENSATION

Subsequent to congressional action improving the pay status of federal employees, the maximum stipend for residents was increased on July 1, 1958. Board, room, and laundry cannot be provided free to residents, and therefore these costs must be deducted from the resident's stipend if provided by the Veterans Administration hospital. Table 56 reveals the current maximum stipends for medical residents. Each deans committee determines the actual stipend level within the permissible maximum.

NATIONAL DEFENSE AND MEDICAL EDUCATION

SELECTIVE SERVICE SYSTEM

The following information, current as of July 1, 1958, has been submitted by the Selective Service System National Headquarters.

The responsibility for primary classification of registrants rests with Selective Service local boards. If a person or his employer (college, medical school, or hospital) has requested his deferment and he has been classified as available for military service, the person or his employer may, within 10 days of the mailing of the notice of classification, file an appeal. The appeal will be reviewed ordinarily by the appeal board having jurisdiction where the registrant's local board is located, but it may be transferred for review to the appeal board having jurisdiction in the area where the registrant is working or attending college if this is requested in writing when the appeal is made. If the state appeal board should sustain the classification, the registrant or his employer may, if there is a dissenting vote in the appeal board, file a written request with the local board to have the decision appealed to the President. If there is no dissenting vote, the state or national director of Selective Service may appeal the case to the president.

The "college student certificate," SSS Form 109, continues to be prescribed for the use of institutions of higher learning, including those of medicine, in furnishing the local boards information regarding registrants who are enrolled as students in those institutions. These forms should be submitted to the local boards by the educational institution on request of the registrant. However, the mere filing of such a form does not constitute a request for occupational deferment, since, in order to establish the right of appeal as an interested party, a written request from the college or employer for occupational deferment must accompany the form. The registrant has the right of appeal if exercised in the prescribed 10 days. He may make his appeal informally in writing.

Eligibility for Consideration for Deferment

The law empowers the President to provide for the deferment of any person whose deferment is equitable and in the national interest. Furthermore, it is the sense of Congress that provision should be made for the annual deferment from training and service of premedical, predental, and allied preprofessional students in numbers equal to those at present (1950) in attendance at colleges and universities as outlined in the general student deferment program.

Sections 1622:15 and 1622:25 of the Selective Service Regulations specify the conditions under which students pursuing programs of higher education may be considered for deferment. Within these specified requirements, students of the healing arts are considered for deferment in the same manner as students pursuing other undergraduate or graduate courses at colleges, universities, and similar schools.

Any student not previously deferred who is pursuing a full-time course of study is entitled to a single period of statutory deferment, class 1-S, until the end of the academic year. Such deferment does not preclude the possibility of later deferment in class 2-S. Students whose activity in study, research, medical, or other endeavors is found necessary to maintenance of the national health, safety, or interest may be deferred in class 2-S until completion of their college training, provided they maintain satisfactory scholastic records. A student who is deferred for study extends his liability for military training and service up to his 35th birthday instead of his 26th, as prescribed for registrants who have never enjoyed a deferment.

TABLE 56.—*Resident Stipends (Maximum)*

	Per Year
Junior resident	$3,250
Intermediate resident	3,515
Senior resident (first year)	4,165
Senior resident (second year)	4,945
Senior resident (third year)	5,545

In selecting a student for deferment in class 2-S, the Selective Service local boards may, at their discretion, be guided either by the score made by the student on the Selective Service College Qualification Test or by his record of academic performance. The college qualification test is given for the Selective Service System by the Science Research Associates, Inc., of Chicago. At present, in order to be eligible for deferment on the basis of this test, an undergraduate student must make a score of 70 or more. SSS Form 108 has been prescribed for furnishing to the local board the score made on this test. This score is confidential and may be divulged by the local board only to the registrant or to one holding his written consent.

To qualify for deferment on the basis of academic performance, the nonprofessional student must have maintained the following standing among the male members of his class: freshman year, upper one-half; sophomore year, upper two-thirds; and junior year, upper three-fourths. A student accepted for admission to medical school after July 1, 1951, for the class next commencing may be deferred, provided that, during his last full-time year at college or university, he was ranked among the upper one-half of the male members of his class or had a score of 70 or more on the Selective Service College Qualification Test.

A student accepted for admission by a graduate school after July 1, 1951, as a full-time student for the class next commencing may be deferred provided that, in his last full-time academic year in a college or university, he achieved a scholarship standing among the upper one-fourth of the male members of his class or scored 80 or more on the qualification test and provided that the graduate school certifies that he is meeting the degree requirements. Decisions concerning deferment of American students enrolled in foreign universities, including medical students, are the responsibility of the local boards. The local board may accept or reject any claims or evidence presented for deferment.

Status of Interns and Residents

The Selective Service System has always recommended the deferment of graduates of medicine to complete one year of internship training. Selective Service has stated that men, to be given favorable consideration for deferment to complete a residency or more than one year of internship, should be absolutely essential to the operation or maintenance of the hospitals where they are employed or that they be among those selected by the surgeon general of the United States Public Health Service and recommended for specialty training necessary in the staffing of the hospitals of the United States Public Health Service. The Selective Service System is of the opinion that there is a sufficient number of young physicians who have satisfied their military liability or who are physically disqualified for military service to satisfy the requirements of the hospitals for residents and to provide for specialty training for civilian needs.

The Selective Service has agreed to recommend to the Selective Service local boards the deferment of men in a number not to exceed 300 as an over-all total for the surgeon general of the United States Public Health Service. It is expected that this program may be continued from year to year.

All young physicians participating in this program are to be commissioned in the reserve component of the Public Health Service, and they are to be selected by the surgeon general of the Public Health Service for such training. The request for deferment is to pass from the individual to the surgeon general of the Public Health Service and then, if recommended, will be forwarded through national headquarters of the Selective Service System to the respective local boards of that system.

Those graduates of medicine who accept a commission in the medical corps reserve of an armed force will not be used, according to present Selective Service policy, to fill a regular call; therefore, such young men who are accepted in the Berry Plan and who accept reserve commissions will be classified by their Selective Service local boards in a class indicating that they are members of the reserve forces. Should it become necessary for the Department of Defense to place with Selective Service a special call for doctors of medicine, such men will then be given consideration for deferment from active duty for such period of time necessary to complete their training.

A young physician who has established himself in a community where he has been found by his local board essential to the maintenance of an adequate medical service in that community may be deferred by his Selective Service local board or such a physician may be deferred for teaching, research, or Public Health work when these are considered by the local board to be essential in the national interest.

For the academic year 1958-1959, the Public Health Service has arranged certain research grants for students who have completed two years in medicine. These grants will be for one year, and the deferment of these special men will be requested by the individual registrant and recommended by the surgeon general, United States Public Health Service.

Status of Faculty Members

No policy has been announced by the Selective Service System on the granting of deferment to faculty members, except that teachers of medicine have been mentioned in a Selective Service Operations Bulletin as being in a critical occupation to which local boards should give special consideration. It has been recommended that as a general policy, essential members of the medical, dental, and veterinary faculties be held in their teaching positions until such time as replacements are found. This recommendation applies especially to persons in the basic science departments. This policy is not a blanket recommendation for deferment from military service for all teachers. Part-time teachers, who devote only a small portion of their time to teaching, will be expected to enter the military services. The President is also directed to establish a national advisory committee to advise the Selective Service System and to assist state and local advisory boards in selecting the needed medical, dental and allied personnel.

Expiration of the "Doctor-Draft" Law

The August, 1957, issue (vol. 7, no. 8) of Selective Service carried a statement regarding the expiration of the "Doctor-Draft" law and the new legislative provisions for "Specialists' Service." Because of its importance from the standpoint of medical education as well as its implication in medical practice, this statement is presented in full in the following paragraphs.

"Doctor-Draft" Law Expires; New Legislation Provides for Specialists' Service

Amendments to the Universal Military Training and Service Act, as amended, adopted in June, 1957, replace the former "Doctor-Draft" law and provide for meeting the requirements of the Armed Forces for medical, dental, and allied specialists until June 1, 1959. Under the new amendments only those specialists who are otherwise liable as regular registrants are subject to induction under the Selective Service Law.

The old "Doctor-Draft" law under which medical, dental and allied specialists had been liable since 1950 expired July 1, 1957. It had placed liability for service on older doctors, dentists, and allied specialists, at one time up to the age of 51.

One of the principal effects of the new amendments to the basic Selective Service Law is to limit liability of doctors, dentists and allied specialists to age 35 for those deferred on or after June 19, 1951, and to age 26 for others. Public Law 85-62, which amends the basic Selective Service Law with respect to these specialists, was signed by the President on June 27, 1957. By placing medical, dental, and allied specialists under the same provisions of law and regulations as other registrants with respect to the upper limit of the age of liability, the 1957 amendments relieve from liability under the Universal Military Training and Service Act, as amended, any such specialist over the age of 32 on the date the amendments became effective—July 1, 1957. This is true because in order to have acquired extended liability under the June 19, 1951, amendments, a registrant must not only have been deferred on or after that date, but also must not have attained the 26th anniversary of his birth by that date. Any man who was 26 on June 19, 1951, would, on July 1, 1957, have been 32 years old.

The amendments in addition provide that

1. No person in the medical, dental, and allied specialist categories shall be inducted if he applies for an appointment as a reserve officer and is or has been rejected for such an appointment on the sole ground of physical disqualification.

2. The President may order to active duty for not more than 24 consecutive months any member of a reserve component who is such a specialist, who is under 35, and who has not performed at least one year of active duty in the armed forces.

3. Any such person called or ordered to active duty from a reserve component of the armed forces and who serves on active duty as a specialist for 12 months or more, shall upon release from active duty or within six months be given an opportunity to resign the commission unless he is otherwise obligated to serve in active training and service in the armed forces or in training in a reserve component by law or contract.

4. Any physician or dentist qualified for a reserve commission shall, so long as need for his services exists, be given an opportunity to volunteer for active duty of not less than 24 months.

5. The President may prescribe rules and regulations for the selection or induction of persons by age group or groups and for the selection and induction of persons qualified in needed medical, dental, or allied specialist categories pursuant to requisitions submitted by the Secretary of Defense.

6. Qualified specialist aliens liable for induction shall not be held ineligible for appointment as commissioned officers solely on the grounds that such alien specialists are not citizens or have not declared their intention of becoming citizens.

7. Any qualified person who is liable for induction, or who is ordered to active duty as a member of a reserve component as a physician, or a dentist, or in an allied specialist category, shall be appointed, reappointed, or promoted to such grade or rank as may be commensurate with his professional education, experience, or ability provided that any person in a needed medical, dental, or allied specialist category who fails to qualify for, or who does not accept, a commission, or whose commission has been terminated, may be used in his professional capacity in an enlisted grade.

8. Periods of active duty performed by such specialists in student programs prior to receipt of appropriate professional degree or in intern training shall not be counted toward establishing the qualification of such specialists for classification as a veteran exempt from liability for training and service.

9. It is the sense of Congress that the President provide for deferment of optometry students and premedical, preosteopathic, preveterinary, preoptometry and, predental students in numbers at least equal to the numbers of such male students now studying in colleges and universities.

10. Public Law 62, 85th Congress, amending the Universal Military Training and Service Act, as amended, to provide service liability for persons in medical, dental and allied specialist categories, expires on July 1, 1959.

With the expiration of the requirement for special registration of medical, dental, and allied specialists, such specialists under the amendments of June 27, 1957, should notify their local boards within 10 days of the attainment of degrees in these fields.

ARMY, NAVY, AND AIR FORCE PROCUREMENT PROGRAMS

The following information summarizing the Army, Navy, and Air Force procurement programs has been submitted by the office of the Assistant Secretary of Defense (Health and Medical), current to June 26, 1958. It has been prepared so as to present a general portrayal of current procurement programs in the medical branches of the armed services insofar as they concern undergraduate and graduate medical education.

Army

EARLY COMMISSIONING PROGRAM FOR MEDICAL STUDENTS

Medical students may apply for commissions in the grade of second lieutenant, Medical Service Corps, Army Reserve, while attending medical school. Students participating in this program will be obligated to accept superseding appointments in the grade of first lieutenant, Medical Corps, Army Reserve, upon graduation and, in accordance with the needs of the active Army may be required to serve on active duty for a period of two years upon completion of internship. Persons appointed under this program are assigned to Ready Reserve Units in appropriate medical corps vacancies in TOE and TD troop program units, USAR Schools, and USAR Control Groups (Annual Training).

Every effort will be made to place officers commissioned under this program on active duty on a date desired by them; however, no assurance can be given that they will be ordered to active duty at a particular time, since such action is contingent upon programmed requirements of the active Army.

Participation in this program will not in itself increase the active service liability or obligation of the participant. However, participants will be required to certify to their understanding that appointment prior to attaining age 26 incurs an obligation for active participation in the Reserve training unless excused under regulations prescribed by the Secretary of the Army.

Clinical Clerkship Training Program

Participants in the Clinical Clerkship Training Program will be medical students at the sophomore-junior and/or junior-senior level, who now hold appointments in the Medical Service Corps, Army Reserve, as lieutenants, or will be commissioned in sufficient time to participate in the program. A limited number may also participate in the program as "student employees" under Civil Service. Students in Army Reserve status who are selected for this clinical clerkship must volunteer to perform not more than 60 days of active duty for training, including travel. Students who are assigned to a USAR Control Group (annual training) and are selected for the clerkship will fulfill their annual requirement for active Reserve participation by performing the above period of active duty for training. The students who are assigned to a TOE or TD Reserve Unit, or a USAR School, will perform this training "in lieu of" the annual unit training (summer camp) requirement with their unit.

The program will consist of approximately eight weeks of instruction at Army teaching hospitals, which will be devoted to military medicine and other military instruction, and the remaining time will be divided into two equal periods, one embracing internal medicine and its subspecialties, the other surgery and its subspecialties. A preventive medicine program will also be available and will include one week of general orientation in military organizaations, its functions and procedures, followed by detailed observation and assistance in a comprehensive preventive medicine program. Research clerkships are also available in a limited number for selected individuals at Walter Reed Army Institute of Research.

The program commences on July 1 each year and is of 45-60 days duration. A student selected for a clerkship between his sophomore-junior year is not eligible to apply for the clerkship between his junior-senior year.

Senior Medical Student Program

Selected senior medical students will be commissioned as second lieutenants, Medical Service Corps, United States Army Reserve, and will be permitted to continue their studies in their respective schools as officers on active duty with full pay and allowances until they complete their academic requirements for the degree of doctor of medicine. Upon completion of their medical education, selected students will be required to accept appointments in the grade of first lieutenant, Medical Corps, U. S. Army Reserve; they must agree to participate in the National Intern Matching Program, Incorporated, and serve on active duty for three years immediately following their civilian or military internship. This includes time obligated under the Universal Military Training and Service Act, if applicable. Participants who are not matched for an Army internship will be released from active duty for one year to allow them to complete a civilian internship, and they will then be recalled to active duty for three years at the end of the 12-month period.

Military Intern Program

Selected graduates of approved medical schools will be commissioned as first lieutenants, Medical Corps, U. S. Army Reserve, and will be ordered to active duty for the purpose of completing a 12-month internship in a military hospital. Individuals participating in the program will not incur obligatory service; however, those individuals who will be liable for military service under the provision of any law will be required to serve that obligation immediately upon completion of their internships. Military interns will be encouraged to apply for Regular Army and residency training.

Applicants must agree to participate in the official cooperative plan of internship appointments for first-year internships as conducted by the National Intern Matching Program, Incorporated.

Military Resident Program

The Military Resident Training Program is established for the purpose of providing the number of specialists required to meet the needs of the Army for career Medical Corps officers. Residencies are sponsored in both military and civilian hospitals.

Officers of the Regular Army Medical Corps and individuals who meet the appointment criteria for the Regular Army are eligible to compete for residency training. Although appointment in the Regular Army is not a requirement for appointment as a resident, the purpose of the program is to provide the Army with sufficient career personnel having the required specialty training. Accordingly, applicants will be considered on the following priority basis: (1) Regular Army Medical Corps officers, (2) Reserve Medical Corps officers on active duty, including interns who are concurrently applying for Regular Army appointment, (3) civilian physicians, including interns, who apply for Regular Army appointment, and (4) all other applicants.

Inasmuch as the number of applications received for participation in the Army residency program far exceeds the number of appointments available, consideration should be given to seeking a Regular Army commission in order to establish a priority for consideration for the residency program. Appointment for the program ordinarily will not be made more than two years in advance, and applications for Regular Army in connection with residency training will not be considered for appointment in a grade higher than captain. Individuals selected for training who have not completed the appropriate Army Medical Service orientation course, or an equivalent period of active duty as a medical officer, as determined by the surgeon general in each case, will be required to undergo such training prior to entering residencies. Selections will be made in November of each year. Appointments to fill remaining vacancies will be made from applications as received. Training in most specialties commences approximately every six months.

Individuals placed in residencies in Army hospitals will be required to serve one year on a duty status for each year of training received.

In the event spaces in the specialty requested are not available in Army hospitals on one of the next two or three starting dates after approval of an application, an opportunity will be offered to applicants approved for Regular Army to obtain residency training in a civilian hospital approved by the Council on Medical Education and Hospitals of the American Medical Association. Individuals participating in the program in civilian hospitals under this policy are required to serve on active duty for two years for the first year of training received and one year for each subsequent year.

Navy

THE ENSIGN 1915 USNR PROGRAM

After passage of the Selective Service Act of 1940, many medical students who were obligated for military service by the Act indicated their desire to affiliate with the Naval Reserve in order to assure that their period of active duty would be with the Navy's Medical Department. To make this possible and to provide deferment from active duty until graduation, the Ensign, Probationary (Medical) Program was established before the onset of World War II. The first appointments late in 1941 were limited to third-and-fourth-year medical students attending class "A" (approved) medical schools. Within a few months, however, the program was expanded to include first-year and second-year medical students, and it has since come to be known as the Ensign 1915 Program.

The number "1915" is a designator used to identify officers within the Department of the Navy by a code system. The first two digits, 19, indicate that the officer is under instruction in a civilian school; the last two digits, 15, indicate an officer of the Naval Reserve.

The qualifications for appointment as Ensign, 1915, are as follows:

A. Sex: Men and Women

B. Age

(1) Candidates with no prior military service should be at least 19 and of such age that upon expected date of graduation, they will be under 33. The maximum age limit with prior active military service may be adjusted on a month-for-month basis, depending upon the number of months of active military service performed, but in no case to exceed 36 months. Applications cannot be accepted from any person who will have passed his or her 36th birthday when he or she becomes eligible for superseding appointment in the Medical Corps, U. S. Naval Reserve following graduation from medical school.

C. Educational

(1) Should be within 120 days of completion of all academic work required for enrollment in medical school.

(2) Should be in attendance or have been accepted for and be within six months or less of the date of the next entering class at one of the American or certain of the Canadian medical schools accredited by the Council on Medical Education and Hospitals of the American Medical Associa-

tion, including approved schools of the basic medical sciences in the United States and Canada. Applications cannot be accepted from students who will attend a medical school in a foreign country other than Canada.

(3) Should NOT have commenced the final year of medical school.

D. Professional

(1) Applicants are required to establish professional fitness and aptitude for the Naval Service through interviews and a review of college and employment records.

E. Physical Standards

(1) Should be found physically qualified for appointment to commissioned status in accordance with established regulations.

The primary objectives of this program are to provide (1) an opportunity for qualified medical students to affiliate with the Naval Reserve as commissioned officers while still in medical school; (2) assurance that these officers will be able to complete their medical studies and internship prior to fulfilling their obligation for active military duty; (3) assurance that, when they do enter the service, it will be within the Navy's Medical Department; and (4) a primary source of qualified candidates for the Naval Intern Program and for the Medical Corps of the Navy and Naval Reserve.

As an added incentive for membership in the Ensign, 1915 Program, there has been established a 30-60 day active duty research clerkship training program at naval research activities throughout the United States. This program provides orientation and indoctrination into medical research as well as on-the-job training for the undergraduate medical student during his vacation from medical school. Full pay and allowances are authorized for these selected officers while so serving on active duty. Medical students who are commissioned as Ensign, 1915 USNR, and who have successfully completed the first year of medical school are eligible to participate in this program. Research clerkships offer a detailed review of the specific research program being conducted at the training activity. A part of the training is spent in each research department, and the trainee serves as an assistant in actual laboratory research on a specific project under way at that time.

Also established are clinical clerkships at Naval teaching hospitals throughout the United States. Beginning July 1 of each year, this program offers quotas for selected medical students who have completed the second year of medical school, 30 to 60 days of active duty for training during vacation from medical school. Clinical clerkships are planned to provide indoctrination and orientation into naval medicine, rotation through the major professional services of a naval teaching hospital, and performance of on-the-job training duties commensurate with the individual's professional attainments.

Normally each year during the summer months a limited number of mature medical students holding commission as Ensign, 1915, are authorized to participate in NROTC-Midshipmen Cruises. Selections for this important training are made from students who have completed at least their second year of medical school with priority being given those who have completed their third year. Trainees receive an excellent indoctrination and orientation into the practices of naval medicine aboard ship under the supervision of experienced medical officers of the Regular Navy and Naval Reserve.

To assist the medical student financially, and to attract future doctors of medicine toward a career in the Navy Medical Corps, the Senior Medical Student Program was authorized by the Secretary of the Navy. To be eligible for participation, the individual student must be an Ensign, 1915 USNR, or agree to accept such an appointment if selected. Further, he must have completed his third year of medical school and be eligible for enrollment in the ensuing year. During attendance in medical school, these officers serve on active duty, receiving the full pay and allowances of their rank. In return for participation in this program, the individual serves one year plus the 24 months obligated by the Universal Military Training and Service Act, as amended.

Here are some important facts concerning the Senior Medical Student Program:

(1) This program is open to qualified students enrolled at medical schools accredited by the Council on Medical Education and Hospitals of the American Medical Association. Students who have completed their second year of medical school may make application for this training at an Office of Naval Officer Procurement. Active duty commences and continues while in attendance during their senior academic year. To be eligible for participation, he must be an Ensign, 1915 U. S. Naval Reserve, or agree to accept such an appointment if selected. A board convened in the Bureau of Medicine and Surgery selects the candidates for participation in this program.

(2) Physical standards of this program are the same as those established for Regular Navy staff corps officers.

(3) Active duty orders are mailed to the student via the Professor of Naval Science or the District Commandant. Active duty commences upon receipt of such orders and completion of proper reporting endorsements.

(4) The student agrees, in writing, to accept a Regular Navy commission, and if a Regular Navy commission is not tendered, to accept an appointment in the Naval Reserve.

(5) In accepting an appointment in the Regular Navy or Naval Reserve, as a result of having active service in the Senior Medical Student Program as an Ensign, 1915, he is obligated to serve on active

duty and to retain the commission for a period of three years. This active service will commence upon completion of not more than 12 months of a civilian or Naval Internship. Providing that the student has 24 months obligated military service to perform, this active duty affords a splendid opportunity to discharge the military obligation and serve an additional year in return for the benefits received in the Senior Medical Student Program. With no obligated military service to perform, upon enrollment in the Senior Medical Student Program, the student obligates himself to serve for the same period of three years.

(6) As a medical student, he receives the full pay allowances of an Ensign, 1915, while so enrolled on active duty. Pay and allowances are based on longevity as follows:

(a) Less than two years and no dependents, he receives $338.58 per month; with dependents (a member of his family or household dependent upon him for financial support) he receives $355.68 per month.

(b) Over two but less than three years and no dependents, he receives $366.28 per month; with dependents, he receives $384.38 per month.

(c) Over three and no dependents, he receives $429.28 per month; with dependents he receives $447.38 per month.

(7) In addition to the pay and allowances, the student is credited with 2½ days of annual leave for each 30 days of active duty served.

(8) The wearing of the Naval uniform is permitted only when authorized by appropriate naval authority.

(9) Timing is very important. An average of four months is required to completely process each application. Feb. 1 each year is the absolute deadline that completed applications must be forwarded to the Bureau of Naval Personnel, Navy Department, Washington, D. C. This is necessary so that sufficient time is given to the board in the Bureau of Medicine and Surgery to pass on the professional qualifications and the board in the Bureau of Naval Personnel to pass on the over-all qualifications of each applicant. Those selected are required to meet the moral, mental, and physical standards of Navy acceptance. All applicants will be notified by individual letter of their acceptance or rejection not later than the first week in May.

NAVAL INTERNSHIPS

Naval internships are 12 months in duration, are rotating in type, and conform in all respects with the requirements of the Council on Medical Education and Hospitals of the American Medical Association. These compare most favorably with the best civilian internships and each year the number of applicants considerably exceeds the number of available naval internships. Internships are offered at the U. S. Naval Hospitals located at Camp Pendleton, Calif.; Oakland, Calif.; San Diego, Calif.; Jacksonville, Fla.; Pensacola, Fla.; Great Lakes, Ill.; Bethesda, Md.; Chelsea, Mass.; St. Albans, N. Y.; Philadelphia; Newport, R. I.; Charleston, S. C.; Portsmouth, Va.; and Bremerton, Wash.

All naval interns are selected and matched to the Navy by the National Intern Matching Program, Incorporated. It is not necessary for the medical student to be a participant in the Ensign 1915 USNR Program in order to apply and be accepted for a naval internship. On the other hand, if the Ensign 1915 USNR candidate does not desire a naval internship, he should list only the civilian hospitals in the order of his preference, and in this way he will not be competing with those who desire a naval internship and who request to be so matched. The Ensign 1915 candidate who is matched to a civilian internship will be placed on inactive duty during the period of his internship, following completion of which he will be called to active duty in compliance with his previous service agreement.

The basic requirements for a naval internship include the following: (1) be a graduate or potential graduate of a medical school approved by the American Medical Association; (2) be a citizen of the United States; (3) be registered with and his name appear in the Official Directory of Students published by the National Intern Matching Program, Inc.; and (4) meet the prescribed physical standards for a commission in the U. S. Naval Reserve.

In order to become eligible for consideration for a naval internship, candidates must first make application for a commission in the Naval Medical Corps. This can be accomplished by visiting or writing to the nearest Office of Naval Officer Procurement or the nearest U. S. Naval Hospital in the continental United States. In applying for a naval internship it is recommended that five (5) naval hospitals be listed in the order of preference. Generally assignments are made from among the first three listed. The candidate applies, as far as the matching is concerned, directly to the Navy and not to the specific hospital. If matched to the Navy every effort is made to place the candidate in his first choice, but if this is not possible he will be assigned to another hospital of his choice. In the matching program the student is matched to the service and not to a particular hospital within it.

Applications for commission in the Naval Medical Corps for intern training are accepted between Sept. 1 and Dec. 1 each year. That portion of the application pertaining to internship is accepted between Oct. 1 and Dec. 1. Early submission of applications is strongly recommended.

Any additional information may be obtained from the Chief, Bureau of Medicine and Surgery, Department of the Navy, Washington 25, D. C.

NAVAL RESIDENCY TRAINING PROGRAMS

Eight U. S. naval hospitals are now approved for residency training in the various clinical specialties of medicine and surgery by the Council on Medical Education and Hospitals of the American Medical Association and by the respective American Specialty Boards. These naval hospitals are located at Chelsea, Mass.; St. Albans, N. Y.; Philadelphia; Bethesda, Md.; Portsmouth, Va.; Great Lakes, Ill.; Oakland, Calif.; and San Diego, Calif. Residency training for medical officers is also actively sponsored by the U. S. Navy in selected outstanding civilian hospitals, schools, and medical centers of the United States in those few specialties wherein the Navy does not operate formalized training programs. U. S. Naval Hospital residency training activities embrace the specialties of allergy, anesthesiology, cardiovascular disease, dermatology and syphilology, general practice, internal medicine, neurology, obstetrics and gynecology, ophthalmology, orthopedic surgery, otolaryngology, pathology, pediatrics, psychiatry, radiology, surgery, thoracic surgery, and urology. Formally approved training in civilian institutions is conducted in plastic surgery, neurological surgery, preventive medicine and public health, and in children's orthopedic surgery.

Medical officers eligible for assignment to duty as a resident are Regular Navy officers and those Reserve medical officers who have completed their active service obligations under the Universal Military Training and Service Act, as amended. Requests for residency training duty should be forwarded to the Chief of the Bureau of Medicine and Surgery, Navy Department, Washington 25, D. C. All such requests are acted upon by the Bureau Advisory Board on professional training matters. This board makes recommendations in accordance with the merits of each case, taking into consideration the professional experience, background, and aptitude of the candidate and the needs of the service in the particular specialty in which training is desired. One year of obligated service is required for each year of training received in a Naval hospital. Two years of obligated service are required for the first year of training received in civilian institutions and one year of obligated service for each successive year so spent.

It is the policy of the Bureau of Medicine and Surgery to continue a resident in training until formal requirements, leading to eligibility to undergo examination by an American Specialty Board, have been met. This procedure will be strictly adhered to in every case where the needs of the service permit, barring national emergencies, provided that such an arrangement remains mutually agreeable and satisfactory aptitude and progress as a resident are demonstrated. The highest priority in the assignment of naval medical officers to residency training is given those who have completed or are about to complete a normal tour of active duty with an operational unit of the U. S. Navy at sea or on foreign shore stations.

OTHER GRADUATE TRAINING FOR NAVAL MEDICAL OFFICERS, INCLUDING THE MILITARY MEDICAL SPECIALTIES

Aviation Medicine.—The School of Aviation Medicine at Pensacola, Fla., convenes four classes annually of approximately 30 students, for didactic instruction in aviation medicine and actual instruction in flight and ground school. Each class is of about six months duration. Upon completion of this course of instruction they are designated naval flight surgeons and assigned to a two-year period of operational duty. Additionally, the School of Aviation Medicine is approved for residency training in aviation medicine. This training may be requested after completion of the two year operational duty assignment and consists of one year of public health at a civilian institution and two years of residency training in aviation medicine at the school in Pensacola. They are then considered board eligible for certification in aviation medicine. Further opportunities are available in several large naval laboratories for work in research related to aviation medicine. The laboratories are located at Johnsville, Pa.; Philadelphia; and the School of Aviation Medicine, Pensacola, Fla. A medical officer interested in the aeronautical aspects would do well to consider this advanced training.

Submarine Medicine.—This military medical specialty supports all phases of underwater operations in the Navy. Training in this specialty is particularly applicable to those having an interest in occupational or preventive medicine and research in physiology. The basic six months course of training includes lectures, demonstrations, laboratory work, practical experience, and cruises in submarines, rescue vessels, and tenders as available. The majority of the course is given at the Submarine School and Medical Research Laboratory at the Submarine Base, New London, Conn. Eight weeks of the six months period is spent at the U. S. Naval Deep Sea Diving School, Naval Gun Factory, Washington, D. C., where the student learns about diving by making dives and about the physiological problems involved through classroom and laboratory periods.

Upon completion of a tour of duty with an operational unit the medical officer may apply for postgraduate training in various fields. He may prepare himself for later certification in occupational medicine by attending the academic year at the University of Rochester and later service in nuclear powered submarines or surface vessels. He may prepare for certification in preventive medicine by attending one of the public health schools and subsequent field duty ashore and afloat. He may prepare himself for a career in research by a postgraduate year at the University of Pennsylvania

College of Medicine followed by duty at naval laboratories and with operational units. Clinical medical specialty training in all fields is available and having served with operational units is an additional credit to one's application.

Research Program.—The Navy offers 60 Navy medical officer billets for military medical research careers. These opportunities embrace basic medical research in aviation medicine, submarine medicine, clinical specialties, amphibious and field medicine, tropical and exotic diseases and in the areas of the medical problems of nuclear, biological, and chemical warfare defense. These 60 billets are distributed among 15 in-service laboratories, strategically located throughout the world, and represent the program indicated above.

Amphibious and Marine Corps Field Medicine.—Recognized as an important military operational medical specialty, this training is conducted at Camp Lejeune, N. C., Camp Pendleton, Calif., and the Marine Corps Educational Center, Senior School, Quantico, Va. This specialty offers valuable training in the methods of sorting (triage), management, and evacuation of mass casualties, research and development of field medical equipment, field sanitation methodology and practices, medical logistic support, large scale medical planning, and efficient patient care in field combat.

Nuclear Medicine.—Graduate courses for medical officers are conducted at several U. S. Naval Hospitals, in affiliation with civilian institutions. Additional graduate courses in radiobiology are sponsored by the Navy for medical officers at Reed College, Portland, Ore., and the University of Rochester, Rochester, N. Y., to meet present and future needs of the Navy for personnel trained in the fields of nuclear propulsion, radiological safety and special weapons effects. Formal long courses for radiology and other residents are conducted in the clinical use of radioisotopes at the U. S. Naval Medical School, National Naval Medical Center, Bethesda, Md. This latter course is approved by the Atomic Energy Commission and is designed to fulfill the needs of those who wish to appear for future examination for certification by the American Board of Radiology, as well as those residents in other specialties who may need to acquire a better understanding of the clinical utilization of radioisotopes in diagnostic and therapeutic procedures.

Air Force

The Air Force is presently sponsoring training programs for senior medical students, as well as internships and residencies in both civilian and military hospitals. Applicants must be United States citizens, be morally, physically, and educationally qualified, and must not be nor have been conscientious objectors. Eligibility varies with each program according to the applicant's age.

THE SENIOR MEDICAL STUDENT PROGRAM

The Senior Medical Student Program offered by the Air Force is available to selected Junior Medical students. The application period for this program is Nov. 1 to March 1 of the junior year. Those selected are commissioned as second lieutenants and are sponsored from the date of matriculation to the date of graduation. Upon graduation they must agree to accept reappointment as first lieutenants and apply for either a military or a civilian-sponsored internship. Those not selected for intern training are released from active duty for one year to intern under private contract. Selected students incur a three-year obligation for sponsorship of the senior year. No additional obligation is incurred if they are selected for a sponsored internship.

AIR FORCE SPONSORED INTERNSHIPS, CIVILIAN AND MILITARY

The Air Force Intern Training Program, begun in 1950, is designed as a Regular Officer procurement program. For the year beginning July 1, 1959, the Air Force plans to sponsor 90 interns in military hospitals, selected through the National Intern Matching Program. The Air Force will also sponsor 80 interns in approved civilian hospitals. To be accepted, applicants must meet general eligibility requirements stated above, must not be more than 32 years of age, and must be graduates of medical schools acceptable to the Surgeon General.

Selection for civilian internships is made periodically by the Office of the Surgeon General on the basis of scholastic standing, physical fitness, and military aptitude and inclination. Applications for sponsored civilian intern training beginning July 1 are closed as of April 1 each year; closing date for applications for training beginning on "off-term" dates is announced by letter annually. For military internships, applications must be submitted not later than Dec. 1. Those selected are appointed effective the date of graduation from medical school as first lieutenant, Air Force Reserve (Medical). Military interns incur a minimum period of obligated service of 24 months and civilian interns, 36 months, regardless of their Selective Service classification. However, their military service obligation under the Universal Military Training and Service Act, as amended, will be discharged concurrently with this service.

Civilian interns are assigned to the hospital at which they have obtained an approved internship. Since the program is designed to cover the normal one-year internships, students who have accepted appointments to internships longer than 12 months are not favorably considered for this program. (They may not accept any remuneration from the hospital.)

Military interns are not assured assignment in any specific military hospital, but almost all are assigned according to their first, second, or third choice. Military internships are of the general rotating type so that applicants gain appropriate experience in various fields of medicine. Training is directed by military and civilian physicians and includes a wide range of clinical material, utilizing modern medical, surgical, and radiological facilities. It provides for one year of formal training in accordance with the requirements of the Council on Medical Education and Hospitals of the American Medical Association and is followed by two years of general medical duty in Air Force installations.

RESIDENCY TRAINING PROGRAM

The Air Force Residency Training Program is normally limited to members of the Regular Air Force and is conducted in both military and civilian hospitals (including nonmilitary government hospitals). For the year beginning July 1, 1959, the Air Force program provides for a maximum of 425 residents, 130 in military hospitals and 295 in civilian hospitals. Approximately 110 first-year residency training spaces are available. The spaces are about equally divided between military and civilian hospitals.

Physicians who enter this program are expected to remain in training until they have completed the minimum formal training requirements of the specialty boards. Applications for residency training and a regular commission may be submitted simultaneously and may be submitted at any time after completion of three months of internship. For each year of sponsored training in a military hospital, the period of obligated service incurred is one year; in civilian hospitals, the obligation is two years for the first year of training and one year for each additional year.

Residency training is available on a competitive basis in all recognized medical specialties according to the needs of the Air Force. The requirements are greater, however, for additional officers trained in general practice, pathology, otolaryngology, psychiatry, neurology, and obstetrics and gynecology. Training in the following specialties is available at the USAF Hospital, Lackland Air Force Base, San Antonio, Texas: anesthesiology, general surgery, internal medicine, ophthalmology, orthopedic surgery, pathology, pediatrics, and radiology. Applications for a Regular Air Force Commission and residency training to begin on July 1 should reach Headquarters USAF not later than Nov. 1. In any event, applications should be submitted not later than eight months prior to the beginning date of residency training.

The Aviation Medicine Specialty Training Program leading to board certification in Aviation Medicine is a comprehensive program of five years' duration. Applicants must be graduates of the Primary Course of Aviation Medicine and have had a minimum of nine months practice as an Aviation Medical Examiner. Applicants must be officers of the Regular Air Force, physically and professionally qualified, and be no more than 34 years of age when the class convenes. Applications must arrive at Headquarters USAF not later than Dec. 1 for entrance into program beginning the following September.

MEDICAL EDUCATION FOR NATIONAL DEFENSE

The following information on the status of Medical Education for National Defense, current to July 1, 1958, was submitted by the office of the national coordinator of the program.

The Medical Education for National Defense (MEND) Program is presently active in 45 of the American colleges of medicine, and 10 additional schools are to be selected for affiliation effective Jan. 1, 1959. Requests for MEND-affiliation have been considerably in excess of the program's ability to expand, and a waiting list for affiliation is maintained.

The 45 schools presently taking part in the program are Albert Einstein, Baylor, Bowman Gray, Buffalo, California (San Francisco), University of California at Los Angeles, Colorado, Columbia, Cornell, Creighton, Duke, Emory, Georgetown, Howard, Illinois, Iowa, Kansas, Louisiana State, Louisville, Maryland, College of Medical Evangelists, Miami, Michigan, Mississippi, New York University, North Carolina, Northwestern, Ohio State, Oklahoma, Pennsylvania, Pittsburgh, Rochester, Stritch, Temple, Texas (Galveston), Tufts, Tulane, Vanderbilt, Vermont, Medical College of Virginia, University of Virginia, Washington University (St. Louis), University of Washington (Seattle), Western Reserve and Wisconsin.

MEND is a function of the MEND Program subcommittee of the Association of American Medical Colleges; it is endorsed by its parent organization, by the American Medical Association Council on Medical Education and Hospitals and the Council on National Defense, and by medical officials of the Department of Defense, Army, Navy, Air Force, Public Health Service, and the Office of Defense and Civilian Mobilization. It has received the approval and cooperation of a wide variety of federal and private medical and educational activities.

The purpose of the program is to encourage the teaching of principles of military and disaster medicine by regular faculty members of our medical colleges. Nothing is mandatory; each faculty is free to accept or reject any part of the program not consistent with the local philosophy of medical education. All emphasis is on medical rather than military topics. It is hoped that the problem of national preparedness in medical education can be solved by interested faculty members on a local basis and under local control rather than through such methods as the establishment of a federal medical school or through direct federal intervention in curricular content.

Annually, MEND sponsors a series of symposia, with these programs being conducted by federal medical personnel for representatives of nongovernmental medical education. During 1957-1958, two programs were conducted: "Management of Mass Casualties" at the Walter Reed Army Institute of Research in Washington, D. C., and "Medical Aspects of Highway Safety" at Ann Arbor, Michigan. The former program attracted 64 participants, and the latter, presented by the Public Health Service, was attended by 102. Each year MEND also conducts an Orientation Tour for deans and coordinators of newly-MEND-affiliated schools, designed to introduce them to current problems and trends in the federal services.

Activities at the 45 colleges have included special lectures, conferences, and demonstrations in the following subjects: surgery of trauma, wound ballistics, war wounds, radiobiology, defense measures to chemical and biological warfare, aviation medicine, management of mass casualties, civil defense responsibilities of the medical profession, infectious disease problems in disaster situations, and others.

The national coordinator of MEND has an office at the Bureau of Medicine and Surgery, Department of the Navy, Potomac Annex, Washington 25, D. C.

AREAS ALLIED TO MEDICINE

SCHOOLS FOR MEDICAL RECORD LIBRARIANS

The Council has worked closely with the American Association of Medical Record Librarians since 1942 in the development of criteria for and evaluation of educational programs in medical record library science. Initial and continued approvals of schools are considered by the Council on the basis of the recommendations of the Committee on Education and Registration of the American Association of Medical Record Librarians, which has an able education director who makes periodic survey-visits to schools. Significant studies to further advance training in the field are being carried out effectively by the American Association of Medical Record Librarians.

Revision of the curriculum currently recommended by the Council and the American Association of Medical Record Librarians is under active consideration. Revisions will be gradually implemented and based upon studies which will not be completed for several years. The following is abstracted from the statement of the American Association of Medical Record Librarians on one of the studies, "The Functions and Education of Medical Record Personnel" carried out by the University of Pittsburgh:

To implement the recommendations of the study, the American Association of Medical Record Librarians proposes to utilize its education consultant, education director and Education and Registration Committee to develop a detailed sample curriculum along the lines proposed to submit to academic institutions interested in establishing medical record science programs. It is suggested that for purposes of evaluation, this method of education be tried in a limited number of colleges and universities.

The proposed curriculum, however, varies radically in its approach to teaching medical record personnel from that currently being used in existing schools. To familiarize directors and instructors with all types of teaching methods, and, also, to develop cooperatively more and better teaching materials, the Association plans to expand its present program of workshops. It proposes, also, to recommend revision of the Essentials for an Acceptable School for Medical Record Librarians (to the Council on Medical Education and Hospitals). As they stand, these Essentials not only preclude the curriculum recommended by this study, but they also conflict with the academic requirements of those colleges and universities which at the present time are affiliated with medical record librarian schools.

The Association appreciates that the proposals so far discussed are long range in nature and cannot immediately meet the acute shortage of trained medical record personnel. Accordingly, it proposes an accelerated in-service training program for medical record personnel which will improve the skill of untrained workers but will in no way produce professional medical record librarians.

As of June 30, 1958, there were 30 approved schools. Student enrollment increased in 1957 to 161 students in the senior class of degree programs and in certificate programs, which represents an 11% increase over 1956. There was a training capacity for 212 students in these programs, but three schools had no students enrolled during 1957. Accordingly, the occupancy rate was 40% for the senior class of 9 degree programs with senior students in 1957 and 85% in the 19 active certificate programs. Since students were separately enrolled in both programs offered by one school, students were enrolled in 28 programs offered by 27 schools. The number of graduates for six degree programs was 34. In addition, there were 105 graduates from 20 certificate programs or a total of 139 graduates from 25 schools in 1957.

Approved schools offer curricula which include theoretical instruction and practical training in hospitals. When the hospital training is sequentially and properly integrated with collegiate studies, a degree is available after four years of study. Among the 10 schools offering degree programs, 7 admit qualified high school graduates, and 3 schools offer a curriculum of 12 months' duration with admission requirements of three years of preparatory collegiate preparation. In the 21 schools offering certificate programs of one year's duration, 15 require two years of college prior to admission. All but two of these 17 schools will also admit graduates from an accredited school of professional nursing of at least three years' duration. A college degree is required for admission into four certificate programs. Lists of approved schools are available from the Council. Applicants should write directly to the Medical Record Librarian-Director of the School.

Schools conducting degree programs usually begin in June, and the majority of certificate programs admit students in September. Tuition ranges from $66 to several hundreds of dollars per year, and one school requires none. Application for approval by a hospital or university should be made to the Council on Medical Education and Hospitals of the American Medical Association.

SCHOOLS FOR MEDICAL RECORD TECHNICIANS

Schools for medical record technicians are conducted to train the medical record technician who, working under the supervision of a qualified medical record librarian or a medical record committee, performs the technical tasks associated with the maintenance and custody of medical records.

As in the case of schools for medical record librarians, the Council has developed educational criteria for and evaluates schools in close collaboration with the American Association of Medical Record Librarians.

The training of medical record technicians should be conducted in acceptable general hospitals having a minimum of 4,000 annual admissions. These admissions should include an adequate distribution of patients in the various clinical services commonly found in general hospitals. Candidates for admission to an approved school should be proficient in typing and preferably also in shorthand. They should have completed the requirements for high school graduation or should have passed a college entrance examination for admission to an accredited college or university. The minimum length of training is nine months and should include theoretical instruction in anatomy, medical terminology, and medical records, with additional practical training in admitting and discharge procedures, indexing, preparation of reports, and other activities associated with the medical record department.

There are 11 hospitals approved by the Council for training medical record technicians. These schools reported a training capacity for 73 students with an enrollment of 58 students and 37 graduates in 1957. Data for 1956 are 10 schools with a training capacity for 69 students, an enrollment of 55 and 37 graduates. Qualified high school graduates are accepted for courses of from 9 to 12 months' duration.

Hospitals should apply to the Council on Medical Education and Hospitals for approval. Special forms will be supplied for this purpose, and, when the required information has been received, the proposed training program will be reviewed in collaboration with the Committee on Education and Registration of the American Association of Medical Record Librarians. The institutions applying for Council approval will, in all instances, receive full information and every possible assistance in the planning and development of training programs in accordance with present standards. There continues to be an acute shortage of qualified medical record librarians and medical record technicians. Excellent opportunities exist for graduating students. Inquiries on career opportunities, registration, and accreditation of qualified medical record personnel should be addressed to the American Association of Medical Record Librarians, 510 N. Dearborn St., Chicago 10.

SCHOOLS FOR MEDICAL TECHNOLOGISTS

In its continuing efforts to assist hospitals in the development of training programs for medical technologists, the Council cooperates closely with the American Society of Clinical Pathologists, the Board of Schools of Medical Technology, the Board of Registry of the Society, and the American Society of Medical Technologists. The board of schools was established by the society in 1949 to serve as the major advisory body to the Council in all matters relating to standards and the evaluation of educational programs. Revisions of the standards occurred in 1941, 1943, 1947, 1949, 1953, and June, 1958. The significant revision is that, effective Jan. 1, 1962, entrance requirements will be increased from two to three years of pretechnical collegiate education. No major change has been made in the 12 months' technical curriculum in the hospital. It is expected that the third year of college will provide emphasis on general education yet also afford, in appropriate balance, selected courses to broaden the students' science background. Schools not currently affiliated with colleges and universities are encouraged to consider affiliation or affiliations whereby a consecutive educational sequence of three years of college and one year of hospital training will lead to a baccalaureate degree. While such affiliation is not required, it is encouraged on the basis of the inherent educational benefits to students and faculties and the favorable experience of currently affiliated hospital schools.

As of June 30, 1958, there were 681 approved schools, or an increase of almost 4% over the 656 schools approved in 1957. Enrollment increased 6% to 3,099 students in 1957 and the number of graduates was 2,285, which represents a 7% increase over 1956. With a student capacity of 5,186, the occupancy rate in 1957 was 60%. The increases in student enrollment and number of graduates reflect the effective recruitment program of the National Committee for Careers in Medical Technology sponsored by the College of American Pathologists, American Society of Clinical Pathologists, and American Society of Medical Technologists and the concerted recruitment activities of the faculties of approved colleges and universities.

Eighty per cent, or 545 training programs, base admission on two years of college; 90 (13%) require three years of preclinical college education; and 46, or 7%, require a baccalaureate degree for admission.

The number of hospital schools with college or university affiliations continues to increase. In 1957, a total of 490 hospital schools (72%) had college or university affiliations. Such affiliations as noted above are strongly encouraged since they stimulate the development of well-organized training programs suitably integrated with the college curriculum and also serve as a continuing source of students. If properly integrated, a degree is available upon completion of three years of college education followed by one year of hospital training in 452 (66%) of the 681 approved schools. Active liaison between the hospital and the affiliated college is strongly recommended through regularly scheduled meetings of an advisory or coordinating committee comprised of representatives from each faculty.

The minimum duration of the hospital course acceptable for approval is 12 months. Ninety per cent, or 616 schools, offer a course of 12 months' duration. The remaining 10% of the programs vary from 12½ to 36 months in length. Tuition is required by 158 (23%) and a minimal breakage fee by 67, or less than 10%, of the schools. Students receive a stipend in 370 (54%). All states, the District of Columbia, the Canal Zone, Hawaii, and Puerto Rico have approved schools. Interested high school students should apply to accredited colleges and universities of their choice; those students in college or with collegiate backgrounds should apply to the pathologist-director of the laboratory school of their choice. Lists of approved schools of medical technology, which indicate those schools that have college affiliations, are available from the Council.

Application for approval of a school for the training of medical technologists should be made to the Council on Medical Education and Hospitals of the American Medical Association. Forms will be supplied for this purpose on request and should be completed by the director of the laboratory requesting this approval. Inquiries regarding the registration of qualified medical technologists should be addressed to the Board of Registry of Medical Technologists, 611 W. Howard St., Post Office Box 44, Muncie, Ind.

SCHOOLS FOR OCCUPATIONAL THERAPISTS

Through a cooperative liaison which began in 1933 on the request of the American Occupational Therapy Association, the Council has developed standards for the education of occupational therapists. These were initially adopted by the House of Delegates in 1935, and subsequent revisions have been approved in 1938 and 1949. Recommendations for periodic revisions of standards and on initial and continued approvals of curricula are submitted to the Council by two advisory groups, the Advisory Committee on Occupational Therapy Education of the Council on Medical Education and Hospitals and the Council on Education of the American Occupational Therapy Association. The recently appointed advisory committee consists of nine physician members nominated by national organizations in the fields of chest diseases, general surgery, internal medicine, neurology, orthopedic surgery, pediatrics, physical medicine and rehabilitation, psychiatry, and medical education. In addition, there are three occupational therapist members nominated by the American Occupational Therapy Association, and its Director of Education serves as a consultant. Surveys of schools are conducted by joint physician-therapist teams and submitted to the advisory groups which formulate recommendations for final action by the Council. Conferences and basic studies are being carried out by the American Occupational Therapy Association, with the assistance of other organizations, to further advance educational opportunities in the field.

As of June 30, 1958, there were 29 approved schools, 1 of which was on a stand-by basis during 1957. Statistics for total degree and certificate student enrollment and graduates for the academic years 1956, and 1957 and 1958 based upon data submitted to the American Occupational Therapy Association are shown in table 57.

Training for an occupational therapist includes a good general collegiate education coordinated with theoretical and technical instruction in occupational therapy and supervised clinical practice in hospitals. Certificate and/or degree recognition are available, and those so recognized have equal professional status. Programs leading to a baccalaureate degree are generally of four years duration, and schools offering this curriculum accept qualified high school students and transfer students. Certificate programs are predominantly 18 months in duration and accept students with a baccalaureate degree. However, since universities have individual policies on transfer students, interested undergraduates are encouraged to contact schools of their choice early in their collegiate careers to determine admission requirements for the certificate and/or degree programs in a given school. Tuition in all teaching centers closely parallels college fees. Most courses begin in September or February. Lists of approved schools are available from the Council.

Table 57.—*American Occupational Therapy Association Statistics for Total Degree and Certificate Student Enrollment and Graduates for the Academic Years 1956-1958.*

Year	Total Student Enrollment	Graduates
1956	4,903	469
1957	4,532	490
1958	4,083	511

Application by schools for approval of an educational program in occupational therapy should be made to the Council on Medical Education and Hospitals of the American Medical Association. Forms will be supplied for this purpose on request. They should be completed by the administrator of the institution requesting approval. Inquiries regarding career opportunities in the field of occupational therapy and the registration of qualified therapists should be addressed to the American Occupational Therapy Association, 250 W. 57th St., New York 19.

SCHOOLS FOR PHYSICAL THERAPISTS

On the request of the American Physical Therapy Association, the Council developed standards that were adopted by the House of Delegates in 1936. The Council, in cooperation with its advisory groups, the Council on Physical Medicine and Rehabilitation of the American Medical Association and the American Physical Therapy Association, has periodically submitted revised standards to the House of Delegates, which were adopted in 1943, 1949, and 1955. In 1955, the Council on Physical Medicine and Rehabilitation became the Council on Medical Physics, with which there continues close liaison on matters pertaining to physical therapy but which no longer functions in an advisory capacity on physical therapy education. Applications of new schools are reviewed in collaboration with two groups, the Advisory Committee on Physical Therapy Education of the Council on Medical Education and Hospitals and the American Physical Therapy Association. The Advisory Committee on Physical Therapy Education consists of nine physician members who are nominated by national organizations representing the fields of physical medicine and rehabilitation, orthopedic surgery, psychiatry and neurology, internal medicine, pediatrics, general surgery, and medical education. In addition, there are three members who are physical therapists, two nominated by the American Physical Therapy Association and one nominated by the American Registry of Physical Therapists. The senior educational consultant of the American Physical Therapy Association attends meetings as a consultant. Surveys of new and existing schools are conducted by joint physician-therapist teams and recommendatory action submitted by the advisory groups to the Council for action. Active liaison which the medical directors, therapist educational administrators, and other members of the teaching faculties in approved schools is being implemented through more frequent periodic surveys.

Table 58.—*American Physical Therapy Association Statistics for Degree and Certificate Enrollment for the Academic Years 1956-1957*

Year and Class	Schools Reporting, No.	Senior (Degree) and Certificate Students Enrolled, No.	Graduates, Total No.
1956 Senior	25	800	701
1956 Certificate	28		
1957 Senior	14	798	750
1957 Certificate	30		

As of June 30, 1958, there were 37 approved schools. On the basis of data reported to the American Physical Therapy Association, fall enrollment statistics for the senior class of degree programs and for the certificate programs and the number of graduates for 1956 and 1957 are shown in table 58.

Certificate and/or degree recognitions in physical therapy are available, and those so recognized have equal professional status. Most schools offer both degree and certificate programs, and either or both recognitions are available, depending upon a student's preparatory collegiate education. Certificate programs are usually 12 months in duration. The courses are open to students with two or three years of college or those who have graduated from a nationally accredited school of professional nursing of at least three years' duration. The majority of degree programs are four years in length and admit qualified high school graduates and transfer students. Interested undergraduates are encouraged to contact the school of their choice early since admission and transfer requirements vary. Tuition varies in accord with university fees and the majority of courses begin in September and February. Lists of approved schools are available from the Council.

Application for approval should be made to the Council on Medical Education and Hospitals of the American Medical Association. Forms will be supplied for this purpose on request. They should be completed by the administrator of the institution requesting this approval. Inquiries regarding voluntary registration of qualified therapists should be addressed to the American Registry of Physical Therapists, 30 N. Michigan Ave., Chicago 2. Information on requirements for state registration or licensure is available from the Board of Examiners of the states concerned. Inquiries regarding careers in the field of physical therapy should be addressed to the American Physical Therapy Association, 1790 Broadway, New York 19.

SCHOOLS FOR X-RAY TECHNICIANS

The Council has been ably assisted by the American College of Radiology, the American Registry of X-ray Technicians, and the American Society of X-ray Technicians in revising criteria for training and evaluating educational programs in x-ray technology. These advisory groups participated in the most recent revision of the standards adopted by the House of Delegates in December, 1955. Particularly encouraged is progressive training in radiation therapy to afford students at least one month's practical experience intramurally or through affiliation.

Schools making application for approval are surveyed by state and regional councilors appointed by the American College of Radiology. Radiologists appointed by the College also periodically resurvey approved schools, and these radiologists are currently revisiting approved schools. Their tremendous and voluntary contribution of time and experience are a major asset in the program. All data are evaluated by the Committee on Technician Affairs of the American College of Radiology and recommendations submitted to the Council for final action.

As of June 30, 1958, there were 557 schools approved by the Council for training x-ray technicians, which represents an increase of almost 8% over the 517 approved in 1957. Enrollment for 1957 increased 901 or 28%, to a total of 4,113 students. The training capacity increased 22% in 1957 over 1956 to a total of 4,848. The number of graduates increased 7% to a total of 2,109 in 1957.

The minimum admission requirement is high school graduation. A total of 539 schools (97%) admit students directly out of high school, 13 schools (2%) require one year of college, 4 schools (1%) require two years of college, and one school accepts only registered nurses.

The length of training in 335 (60%) is 24 months, 12 months in 129, (24%), 18 months in 59 (10%) and varies from 13, 14, 15, 36, and 48 months in 5%. Five schools offer two courses of 12 or 24 months duration. Tuition is required by 193 (35%) and 73 pay students a stipend. Collegiate affiliations have been established by 181 (35%) of approved schools. Students should apply directly to the radiologist-director of an approved school. Lists of approved schools are available from the Council on request.

Applications for approval of schools of x-ray technology should be submitted to the Council on Medical Education and Hospitals of the American Medical Association, 535 N. Dearborn St., Chicago 10. Inquiries regarding registration of qualified x-ray technicians should be addressed to the American Registry of X-ray Technicians, Metropolitan Building, Minneapolis 1.

THE PURPOSE OF A MEDICAL SCHOOL

IN THEIR introductory statement Sheehan and Taylor [1] indicated that the training of the physician, the search for new knowledge, and the care of the sick are the inseparable threefold facets which constitute the mission of a medical school. It is only through long training in the scientific methods of investigation and by actual care of patients that medicine can be passed on to succeeding generations. Research, which is the background of progress in medicine, turns to the medical school for its investigators and to patients for its problems, with the future of medical care dependent on the production of a continuing supply of physicians and the potentialities of new discovery. "The purpose of a medical school . . . can only be achieved by endeavor in all three directions—medical education, research, and community care—and they must be carried on simultaneously, for they are wholly dependent upon each other, not only for inspiration but for their very means of success."

Every school has the duty and obligation to strive for excellence in each of its three functions to the extent of its individual potentials. There can be no question but that the quality of medical education and research determine the standard of medical care which the nation is to enjoy. It is also true that medical care will be only as good as the men and women who are responsible for it. Thus, in the overall chain of responsibility leading to the objective of preparing medical students, interns, residents, and graduate physicians to render the best possible medical care, the medical schools play key roles as guardians of the health of the community.

If this guardianship is to be fully effective it is essential that those responsible for the conduct of modern medical schools recognize the continuing challenge with which they are confronted. To make the role of the medical schools achieve maximum potential it is vitally important that the medical profession recognize and support the efforts of the schools to meet the challenges presented to them by these threefold areas of responsibility.

The past two generations have witnessed such rapid strides in medical knowledge that the very nature of medical practice and many phases of medical education have been altered. At the present time there is every reason to believe that the next two generations will witness even greater advances in knowledge and continuing dramatic changes in medical practice. Medical education will face challenges to test the ingenuity and imagination of its most outstanding leaders. Many diseases common three decades ago are rarely observed today, while others present increasingly frequent and provocative problems. Along with the changing panorama involved in prevention, diagnosis, and therapy there are also the tremendous challenges presented by changing social and economic characteristics and trends which hold significant implications for medical care and medical education. It is of great importance that these problems and challenges be as clearly defined as the changing scene permits and that they be objectively studied in proper perspective. Their solution should be continuously sought through the mutual efforts of all individuals and organizations concerned with medical education, research, and care. One of the major purposes of a medical school should be to endeavor to inculcate in its faculty and in the students who represent the physicians of the future an acceptance of the constancy of change and the challenge for constructive adventure which it affords if medical education and medical care as well as research are to effectively meet the needs of the changing scene.

THE FULL-TIME FACULTY DEFICIT

During the past several years the annual report on Medical Education in the United States and Canada has included an analysis of the budgeted, unfilled full-time faculty positions in medical schools in the United States. The report for last year indicated a total of 331 such vacancies for 1956-1957, an increase from 258 in 1954-1955 and from 251 in 1955-1956. Tables 16 and 17 in the text of this report present a departmental analysis of both new and old budgeted unfilled full-time faculty positions, which total 619 for 1957-1958. This increase of approximately 90% of such vacancies in the interval of a single year presents a problem of major concern to medical education. Its magnitude, unless the trend is reversed, has developed to the point where it may jeopardize certain aspects of medical education, research, and care in the period that lies ahead.

---

[1] Sheehan, D., and Taylor, H. C., Jr.: Introduction to Mission of Medical School, ed. 2, revised, New York, New York University Press, 1950.

Although some of the increase in budgeted, unfilled full-time faculty positions represents additional needs presented by newly developing institutions, this circumstance accounts for a relatively small number of the vacancies reported. In 1957-1958 all newly budgeted unfilled full-time positions totaled 196, of which 71 were in the basic medical sciences and 125 in the clinical areas. This represented a total increase of 48 over the 148 reported in 1956-1957 when there were 55 such vacancies in the basic medical sciences and 93 in the clinical departments. The major, and most alarming, aspect of the current report for 1957-1958 lies in the number of old (not newly created) budgeted, unfilled full-time faculty positions. In the basic medical sciences the number had increased to 168 for 1957-1958 as compared to 89 in 1956-1957. In the clinical departments there were 255 such unfilled positions in 1957-1958 compared to 94 in 1956-1957.

Those concerned with medical education are confronted with a challenge necessitating serious analysis, together with the development of the means of resolving this problem in the future. There is general indication of the need for increasing facilities for medical education which will reflect itself in the need for larger numbers of adequately qualified full-time faculty personnel in both basic medical science and clinical areas. Thus, medical education finds itself on the horns of a dilemma with the medical schools now in operation unable to fill the existing full-time faculty positions while at the same time advocating the development of new schools which will necessitate many additional full-time faculty personnel.

What has been responsible for this problem? Why are so many budgeted full-time faculty positions unfilled? What can be done to reverse the trend of the past few years and eventually to resolve the personnel problem it has created? These and many associated questions merit careful study and require definitive action. There are more people engaged in medical research today than ever before but the competition for qualified personnel in this area constantly increases. The tremendous expansion of research programs in such organizations as the Public Health Service (National Institutes of Health), the pharmaceutical industry, and other organizations have presented competitive opportunities for personnel in basic sciences. Economic competition in the form of laboratory activities or private practice undoubtedly continues to play a significant role. With due regard to these and other factors, the fact remains that the problem of obtaining and maintaining adequate full-time faculty personnel for those disciplines where such personnel are essential to the teaching and research activities of modern medical schools represents a constant and increasingly difficult challenge. Failure to meet it may seriously interfere with the ability of medical education to maintain and advance its standards as well as prevent the successful expansion and development of needed new facilities. The challenge is one that cannot be ignored.

BALANCES TO BE CONSIDERED IN INTERNATIONAL EDUCATIONAL EXCHANGE OF MEDICAL STUDENTS

In its presentation of the section of the annual report on medical education dealing with International Educational Exchange in Medicine, the Council on Medical Education and Hospitals has published two tables (47 and 49) which are worthy of careful thought. The data in these tables indicate that for every foreign student receiving his basic medical education in the United States, there are seven United States students undertaking medical studies outside of this country and Canada.

In all fields of higher education, the quality of the students and the educational program are of major significance in determining the level of educational objectives that can be achieved. Because of the close relationship between the product of medical education, the physician, and the health and welfare of the public, there must be a peculiar concern with these qualitative factors in medicine.

Admissions policies of medical schools in the United States generally make it difficult for any but unusually competent students from other countries to be accepted. The foreign student who gains a position in a United States medical school wins that place by successfully competing with United States students and, because of restrictions of admissions policies, most often he has competed with the more able United States students. Thus, the relatively few foreign students in United States medical schools in general represent a rather high quality of scholastic achievement and potential. Their academic achievement can usually be judged against a familiar yardstick since they commonly have had at least a part of their college preparatory studies in the United States.

Since World War II, in comparison with foreign students enrolled in United States medical schools, there has been an increasingly large number of United States students studying medicine abroad. In the years immediately after the war, the numbers of United States students seeking careers in medicine exceeded the available positions in our schools. During this period, there undoubtedly were many students who, although qualified for medical study by our usual standards, could satisfy their career plans only by gaining admission to medical schools in other countries. In the past six years, on a national basis, the number of qualified students desiring places in our medical schools has not been excessive to the number of places available.

In the face of this relative equilibrium between United States medical school positions and students interested in and competent for medical study, there continues to be a growing number of American citizens undertaking basic medical study abroad. Undoubtedly, a portion of these students are primarily motivated by a desire to join preparation in medicine with the opportunity for cultural enrichment afforded by foreign study. On the other hand, it seems likely that many of the American students enrolling in foreign medical schools do so because they have not been considered fully qualified for admission to medical schools in this country. Of the many inquiries received by the Council on Medical Education and Hospitals from students contemplating medical study outside the United States and Canada, it has commonly been evident that the inquirer has made earlier, unsuccessful attempts to enter medical schools in this country.

The stakes in the international exchange of students, when considered in their broadest implications, are of imposing significance. Medical exchange involves not only these broad political and cultural considerations but also the narrower, yet very important, consideration of the immediate and future impact of the exchange on health care. At the medical student level, there may be reason for concern that our side of the balance as the sending nation is maintained more by quantitative weight than the receiving side of the balance, which appears to be weighted more by qualitative factors.

FUNNEL CHEST

References to funnel chest in the literature are increasing because of a change in attitude toward indications for operative treatment and some controversy regarding the best type of operation. This apparently hereditary anomaly results from a failure of normal development of the anterior portion of the diaphragm. Earlier writers considered attempting surgical correction only in patients who showed evidence of cardiorespiratory embarrassment, but with modern advances in chest surgery the indications have been greatly liberalized. Although improvement of the appearance of the chest may not be very important in itself, Sutherland[1] called attention to the bad psychic effects in a child of having a deformity that is all too obvious in a gymnasium or natatorium. These children become shy, withdrawn, and depressed. The rapid improvement in personality after surgical correction is itself a sufficient justification of the procedure.

In addition to psychic symptoms funnel chest is associated with such postural disorders as an upper thoracic kyphosis, protuberant abdomen, and forward displacement of the neck and shoulders. In severe cases the patient cannot cough effectively and so becomes prone to chronic bronchitis and bronchiectasis. If not corrected the deformity slowly progresses throughout childhood, and the heart becomes displaced to the left. Functional murmurs and cardiac arrhythmia are commonly observed and the electrocardiogram shows right axis deviation.[2] Although pulmonary function is not severely hampered, these patients often have poor physical endurance. Surgical correction not only relieves cardiorespiratory embarrassment when present but also improves posture if performed at an early enough age. Although patients may be operated on for this condition at any age, the operation for infants devised by Brown has been generally abandoned. Ravitch[3] stated that the earlier the condition is corrected the better, the youngest patient in this series being 3 months old. Others[4] preferred to wait until the child is between 3 and 5 years of age.

Sutherland found that preoperative physiotherapy and postural corrective measures were of little or no value. He stated that in children 3 to 5 years of age if the deformity is not too severe it is necessary only to divide the xiphoid and the strong retrosternal ligaments from the sternum. In older children a wedge-shaped osteotomy is performed at the point of sternal angulation sufficient to produce a slight overcorrection. The periosteum is sutured and with healing the overcorrection disappears. Ravitch stated that no external traction is needed in children. He resected from three to five costal cartilages bilaterally. Holmes[4a] did not resect the costal cartilages but restored their normal shape by means of wedge osteotomies at the costochondral junctions and used a Steinmann pin to maintain external traction. In his series Daniel[5] used external fixation on the first two patients then gave it up as wholly unnecessary. Although either a transverse or a midline incision may be used Baronofsky[6] stated that a transverse incision under the breasts gives the most inconspicuous scar and has less of a tendency to keloid formation than a longitudinal scar.

Sutherland encouraged deep breathing exercises as soon as the child came out of anesthesia and this was continued twice daily. He stated that the chest wall was firm in two weeks, after which postural exercises should be given for a prolonged period. In addition to improvement in posture and mental outlook these children show a marked increase in exercise tolerance. Their dyspnea and cardiac arrhythmia disappears. These results more than justify the operation.

ORGANIZATION SECTION

STATEMENT REGARDING H. R. 12738, 85TH CONGRESS, APPROPRIATION FOR MILITARY DEPENDENTS BEFORE SENATE COMMITTEE ON APPROPRIATIONS

I am Dr. Hugh H. Hussey of Washington, D. C., Dean of Georgetown University Medical School. I am appearing here today as a member of the Board of Trustees of the American Medical Association to discuss the medical care program for the dependents of members of the uniformed services. Since the inception of the program, I have been a member of the Department of Defense Dependents' Medical Care Advisory Committee.

As passed by the House of Representatives, Section 633 of H. R. 12738, 85th Congress, the Department of Defense appropriation bill contains a ceiling on expenditures which we feel could destroy the Medicare program. It appears from the printed Hearings of the House Appropriations Committee that the inclusion of this section was recommended in an effort to force the Defense Department to care for more dependents in military medical facilities where, the committee stated, the cost would be considerably less than in civilian facilities. Later in this testimony, we shall point out that it has not been established that military dependent medical care can be provided more reasonably than civilian care.

Officers in charge of Medicare have concluded that administering the program under the present language of the appropriations bill would be extremely difficult, if not impossible. In any event, they report that the inclusion of the section would necessitate many major reductions in the benefits now offered to the thousands of dependents who live too far away from military bases to be cared for in military facilities.

As developed in the hearings, before public law 569, 84th Congress, was enacted, 40% of dependents were not receiving any form of medical care provided by the government through the military program. Under the old program, therefore, there was a great disparity in the medical services being obtained by dependents of the members of the various uniformed services—indeed, even among dependents of members of the same service.

It was pointed out by representatives of the Department of Defense that this disparity in benefits contributed to the expensive and rapid turnover of trained personnel in the uniformed services. Recognizing this problem, Congress stated in public law 569 that "the purpose of this Act is to create and maintain high morale throughout the uniformed services by providing an improved and uniform program of medical care for members of the uniformed services and their dependents." This committee has been advised by the Department of Defense that, to date, public law 569 has achieved its purpose, and the Medicare program has brought about a definite improvement in the morale of all uniformed personnel, particularly those who are married.

With some exception the American Medical Association has been pleased, in general, with the way the Medicare program has progressed since it began. We believe the program has been successful, in large measure, because representatives of the armed forces and the medical profession have cooperated closely and because dependents of service personnel have been permitted to choose freely between military and civilian sources of medical care.

The total number of dependents cared for in both military and civilian programs showed an overall increase of 39% since the civilian program was enacted in 1956.

In the first 18 months of the program, less than half of the dependents were cared for in civilian facilities by private physicians. As reported in the House hearings, 43.6% of this group resided too far from a military facility; 14.9% required a type of care not available at the military facility; for 12.8% the military facility was inadequate or overcrowded; 5% required emergency care; the remaining preferred civilian facilities for diverse reasons, including those for whom civilian physicians or hospitals were more convenient.

The Department of Defense reported in the hearings before the House Appropriations Committee that of the dependents receiving care in civilian facilities, 41.4% were maternity cases, 9.5% gynecological conditions, and 22.2% involved tonsillectomies. The tonsillectomies performed included a very large backlog which existed when the program was first enacted.

This same report showed that maternity and gynecological cases, according to several analyses of the Medicare program, constituted the major element of cost and frequency of utilization of both military and civilian facilities.

On the question of comparative costs of medical care for dependents in uniformed services and civilian facilities, it has been claimed in the House Appropriations hearings and before this committee that medical costs in the civilian program are far greater than in the military. We know of no valid studies that have been made by the Department of Defense which accurately compare these costs. To our knowledge, the department has no cost accounting system which isolates the cost of medical care for the dependent patient, particularly the total overall costs of maternity and surgical care.

This committee's attention should be called to the fact that outpatient care is not authorized on the civilian side of the program except for emergencies and obstetrics, although outpatient care is authorized in military facilities. Hence the doctors' fees for surgery and deliveries, including preoperative and postoperative care, and all outpatient care for obstetrics are charged against the per diem cost for a few days in civilian hospitals. For example, a physician's delivery fee would be prorated against a four-day hospital stay, or $31 a day for physician's services alone; whereas, he may have cared for this patient for nine months and will follow up the case later in his office—all for one fee.

Obviously, when the Air Force states that it can provide care for additional dependents on the basis of $10 per day, and the Navy for $16, which we must interpret to mean chiefly for obstetrics and surgery, they are not including outpatient prenatal and postnatal and preoperative and postoperative costs in arriving at these cost figures. Indeed, last year, as a result of similar claims made by the military services before the Appropriations Committees, the Bureau of the Budget, in reference to the cost of medical care in military facilities, stated in a letter of June 11, 1957:

"The military hospital operating costs include only direct costs, omitting many items of expense which, for budget and management purposes, need not be included in a Federal cost reporting system. The rate of $27.50 per day established by the Bureau of the Budget for the purpose of reimbursement between appropriations when dependents of one service are provided care in another service's hospitals does not reflect the true hospitalization cost to the Government.

"At least the following items of expense need to be added to arrive at an approximation of the full cost: depreciation of buildings and fixed equipment; outpatient care incidental to hospitalization; maintenance of a centralized procurement and depot system; maintenance of training facilities directed to increasing proficiency of hospital personnel; and management and professional direction by headquarters' staffs. While the Government is in effect a self-insurer against property and liability damages, such expenses cannot be excluded from a computation of total cost of patient care."

The Budget Bureau letter went on to say:

"There should also be included the costs of fringe benefits provided personnel. Such benefits for military personnel include free life insurance, medical care for the serviceman and his dependents, noncontributory retirement, as well as a number of minor benefits which are not susceptible to cost analysis. The Government also contributes toward the retirement and life insurance of its civilian personnel. While we have included certain of the fringe benefits in our computations, you can appreciate our concern that their costs not be regarded as definitive.

"Working with limited information and conceding that cost analyses of these expenses are not maintained, we have estimated that the above components of hospital expense contribute the following approximate amounts to the cost per patient day of providing care for dependents in military hospitals: depreciation, $1.25; outpatient care, $3.00; supply overhead, 0.45; education and training, 0.85; headquarters overhead, 0.20; liability and property insurance, 0.20; fringe benefits—life insurance, medical and dental care, and retirement—1.70, 0.45, and 0.50, respectively; total, $8.60. If these costs were added to the $27.50 uniformed service reimbursement rate, the total expense would approximate $36."

At the meeting on May 9, 1958 of the Dependents' Medicare Advisory Committee to the Secretary of Defense, a representative of the Bureau of the Budget reported that a survey was being completed which would bring up to date the figures furnished last year. Since May, there has also been an additional cost factor to consider, based on the military and the civilian pay raises recently enacted which will affect the estimates for these costs for fiscal year 1959. These studies by the Bureau of the Budget have now been completed and indicate that the per diem cost for a dependent patient in military facilities will approximate $44. A copy of the Bureau of the Budget's letter of June 27, 1958 is attached for the committee's information. I will appreciate your making it a part of the record.

Whether or not the cost is higher in a civilian facility, and we do not feel that it is, the program nevertheless has done what the purely military medical program could not do—it has cared for those dependents not residing near a military installation, others not residing with their sponsors, and those residing where adequate military facilities are not available.

It has always been our belief that any Dependents' Medical Care Program in the armed services should allow the dependent a free choice of physician and hospital and should not be the basis for an expansion of military medical facilities. We have opposed such expansion of military medical facilities and military medical care activities because of the resulting necessity for the drafting of additional physicians under admittedly discriminatory legislation. In our opinion, if the present restrictions are retained in Section 633, both of these objectives would be defeated.

We feel that if the Congress sees fit to continue to provide, or to expand, medical care for the dependents of members of the armed forces, the services of civilian physicians and hospitals should be used wherever possible, to be paid for at prevailing rates, with provision for free choice of physicians. In our opinion, this is a sound, fair and workable position. It is one which has been tested and one which will benefit the service personnel and their dependents, relieve the unnecessary strain on the military medical services, and aid in the orderly development of community medical services for all of the people.

If the restrictions now in the bill are retained, there will also be a serious effect on service morale. In this connection, it should be remembered that the Dependents' Medical Care Act was instituted less than two years ago by the Congress primarily to attract and keep valuable personnel in the armed forces by giving them one of the fringe benefits that make business and industrial careers attractive.

This program, which is in the nature of a fringe benefit, whose purpose is to maintain high morale in the uniformed services and to encourage more men to enter and remain in a military career, should not be reduced or eliminated. We believe, with Secretary Brucker and the Department of Defense, that the action in setting a limitation on obligations for civilian medical and hospital care for dependents could cause the eventual destruction of the Medicare program.

It does not seem to us to be in the interests of National Defense to destroy one program in order to save 30 million dollars, while, at the same time, provide a military pay raise program costing 600 million dollars when both programs have the same objective.

We recommend, therefore, that Section 633 be eliminated from the House Defense Appropriation bill.

Mr. Chairman, I thank you and the members of the subcommittee for the opportunity of appearing at this hearing.

ANNUAL MEETING, ATLANTIC CITY, JUNE 8-12, 1959

The Scientific Program for the Annual Meeting of the American Medical Association in Atlantic City, June 8-12, 1959, is rapidly taking shape. There will be a full week of lectures, panel discussions, symposiums, motion pictures, color television, and scientific exhibits.

The lecture program for each section of the Scientific Assembly is prepared by the secretary of the section. A prospective participant should communicate at an early date with the secretary of the section before which he wishes to read a paper. The deadline for submission of titles of papers is Dec. 15.

The Scientific Exhibit is arranged by the Council on Scientific Assembly in cooperation with the Representatives to the Scientific Exhibit from the sections. Application blanks for space may be obtained from the section representatives or from the Secretary of the Council on Scientific Assembly. The deadline for submission of application is Jan. 10, 1959, but applicants are urged to send in applications as early as possible before that time.

Application blanks for time on the motion picture program are available also and may be obtained from the Secretary, Council on Scientific Assembly. Films are subject to preview at the discretion of the Council. The deadline is Jan. 10, 1959.

Following are the addresses of the section secretaries and representatives to the Scientific Exhibit from the sections:

Anesthesiology

Secretary—Vincent J. Collins, M.D., New York University-Bellevue Medical Center, 550 First Ave., New York 16.

Exhibit Representative—Edwin L. Rushia, M.D., University Hospital, Augusta, Ga.

Dermatology

Secretary—Edward P. Cawley, M.D., University of Virginia Hospital, Charlottesville, Va.

Exhibit Representative—Stanley E. Huff, M.D., 636 Church St., Evanston, Ill.

Diseases of the Chest

Secretary—Burgess L. Gordon, M.D., The Lovelace Foundation, 4800 Gibson Blvd., S. E., Albuquerque, N. Mex.

Exhibit Representative—Edwin R. Levine, M.D., 111 N. Wabash Ave., Chicago 2.

Experimental Medicine and Therapeutics

Secretary—Elliot V. Newman, M.D., Vanderbilt University Hospital, Nashville 5, Tenn.

Exhibit Representative—Joseph F. Ross, M.D., Department of Nuclear Medicine and Radiation Biology, University of California School of Medicine, Los Angeles 24.

Gastroenterology and Proctology

Secretary—William H. Dearing, M.D., 200 First St., S. W., Rochester, Minn.

Exhibit Representatives—Willard H. Bernhoft, M.D., 2900 Main St., Buffalo 14, and George Gordon McHardy, M.D., 3636 St. Charles Ave., New Orleans 15.

General Practice

Secretary—E. I. Baumgartner, M.D., 25 Alder St., Oakland, Md.

Exhibit Representative—I. Phillips Frohman, M.D., 2924 Nichols Ave., S. E., Washington 20, D. C.

Internal Medicine

Secretary—Rudolph H. Kampmeier, M.D., Vanderbilt University School of Medicine, Nashville 5, Tenn.

Exhibit Representative—Henry T. Ricketts, M.D., 950 E. 59th St., Chicago 37.

Laryngology, Otology, and Rhinology

Secretary—Walter E. Heck, M.D., Stanford University Hospital, San Francisco 15.

Exhibit Representative—Walter H. Maloney, M.D., University Hospitals, 2065 Adelbert Rd., Cleveland 6.

Military Medicine

Secretary—Col. Charles H. Bramlitt, M.C., U. S. A. F., Directorate of Professional Services, Office of the Surgeon General, Washington 25, D. C.

Exhibit Representative—Capt. Robert V. Schultz, M.C., U. S. N., Bureau of Medicine and Surgery, Department of the Navy, Washington 25, D. C.

Nervous and Mental Diseases

Secretary—A. L. Sahs, M.D., University Hospitals, Iowa City.

Exhibit Representative—Benjamin Boshes, M.D., Northwestern University Medical School, 303 E. Chicago Ave., Chicago 11.

Obstetrics and Gynecology

Secretary—Keith P. Russell, M.D., 511 S. Bonnie Brae St., Los Angeles 57.

Exhibit Representative—Frederick H. Falls, M.D., 715 Lake St., Oak Park, Ill.

Ophthalmology

Secretary—Harold G. Scheie, M.D., 313 S. 17th St., Philadelphia 3.

Exhibit Representative—Frank W. Newell, M.D., 950 E. 59th St., Chicago 37.

Orthopedic Surgery

Secretary—Robert J. Joplin, M.D., 1180 Beacon St., Brookline 46, Mass.

Exhibit Representative—James I. Kendrick, M.D., 2020 E. 93rd St., Cleveland 6.

Pathology and Physiology

Secretary—Hugh A. Edmondson, M.D., 1200 N. State St., Los Angeles 33.

Exhibit Representative—Samuel A. Levinson, M.D., L. A. Weiss Memorial Hospital, 4646 N. Marine Dr., Chicago 40.

Pediatrics

Secretary—Arild E. Hansen, M.D., 812 Mechanic, Galveston, Texas.

Exhibit Representative—F. Thomas Mitchell, M.D., LeBonheur Children's Hospital, Memphis 5, Tenn.

Physical Medicine

Secretary—Earl C. Elkins, M.D., 200 First St., S. W., Rochester, Minn.

Exhibit Representative—Harold Dinken, M.D., 1756 Race St., Denver 6.

Preventive Medicine

Secretary—Frank Princi, M.D., University of Cincinnati College of Medicine, Cincinnati 19.

Exhibit Representative—Paul A. Davis, M.D., 633 E. Market St., Akron 4, Ohio.

Radiology

Secretary—Traian Leucutia, M.D., Harper Hospital, Detroit 1.

Exhibit Representative—Richard H. Chamberlain, M.D., 3400 Spruce St., Philadelphia 4.

Surgery, General and Abdominal

Secretary—Gustaf E. Lindskog, M.D., 333 Cedar St., New Haven 11, Conn.

Exhibit Representative—Julian Johnson, M.D., 3400 Spruce St., Philadelphia 4.

Urology

Secretary—Edward H. Ray, M.D., 203 W. Second St., Lexington, Ky.

Exhibit Representative—E. F. Poutasse, M.D., Cleveland Clinic, 2020 E. 93rd St., Cleveland 6.

NOMINATIONS FOR GENERAL PRACTITIONER AWARD

Nominations for the General Practitioner of the Year award should be submitted to the American Medical Association headquarters as soon as possible. The award winner is chosen from nominations made by the constituent societies. Final selection is made by a committee appointed by the Chairman of the Board of Trustees. The winner will be announced Dec. 2 at the opening session of the House of Delegates at the Minneapolis Clinical Session.

COUNCIL ON MEDICAL SERVICE

COMMITTEE ON MATERNAL AND CHILD CARE

Conference on Perinatal Mortality and Morbidity Study Programs.—On July 26 and 27, the Committee on Maternal and Child Care of the Council on Medical Service sponsored a conference to develop recommendations for a basic flexible program that may be used by state and county medical societies, state and local health departments, and individual hospitals in their efforts to reduce deaths and morbidity resulting from conditions of the perinatal period. Participating in the conference were representatives of the College of American Pathologists, the American College of Obstetricians and Gynecologists, the American Association for Maternal and Infant Health, the Children's Bureau, the Association of State Maternal and Child Health and Crippled Children Directors, the American Academy of General Practice; the American Academy of Pediatrics, the National Institute of Neurological Disease and Blindness and the Human Embryology and Development Study Section of the National Institutes of Health; the American Hospital Association, the American Society of Anesthesiologists, and the American Public Health Association.

The immediate objective of the conference was to develop a set of guides for perinatal study committees similar to those developed last year for maternal death study committees. Since perinatal study committees now exist in individual hospitals, on a city-county-wide basis, and on a statewide basis, one of the early tasks of the conference was to make certain that the guides would be suitable to the needs of all three. Some of the most difficult decisions to make had to do with terms, definitions, and the calculation of rates to be used in study programs involving perinatal mortality and morbidity.

During 1957 and early 1958 the Committee on Maternal and Child Care sponsored field studies of many statewide, citywide, and individual hospital perinatal mortality study programs. It also held two regional conferences, one in Philadelphia and the other in Chicago. With these as a background, and the conference July 26 and 27, the Committee hopes to complete its guides late this fall.

POSITIVE HEALTH PROGRAM FOR SENIOR CITIZENS

Proceedings Available:—Numerous requests have been received for copies of papers presented at the A. M. A. Planning Conference for Medical Society Action in the Field of Aging, held in Chicago, Sept. 13-14, 1958, as well as the "A. M. A.'s Positive Health Program for Senior Citizens." A full report on the Conference, including all addresses, and the Positive Health Program will be available about Nov. 20, 1958. Physicians desiring copies may send their requests to: Council on Medical Service, American Medical Association, 535 N. Dearborn, Chicago 10.

MEDICINE AND THE LAW

TAX DEDUCTION OF PROFESSIONAL ENTERTAINMENT EXPENSES

The Central Medical Society of Jackson, Miss., has received the following ruling from the District Director of the Internal Revenue Service in Jackson setting forth the most detailed statement regarding the deduction of physician's entertainment expenses that has come to the Law Department's attention.

Following is the answer to the questions in your letter of June 4, 1958, concerning the deductibility, for federal income tax purposes, of doctors' entertainment expenses. We have no objections to this information being passed along to other physicians.

1. A physician may deduct on his federal income tax return the costs of entertainment, provided he can establish to the satisfaction of the Internal Revenue Service, by appropriate evidence, that such expenses are ordinary and necessary business expenses and clearly related to the production of business income.

2. The amount of the deduction must be proved and its reasonableness determined. Once the amount is established, the deduction may be claimed when the doctor is able to show that the entertainment had a direct relationship to the conduct of his practice and can show the business benefit reasonably to be expected from the expenditure. The general statement that he hoped or expected to get referrals or patients as a result of the entertainment is not enough. If personal reasons predominate, the expenditure may not be deducted, even though there is some possibility of a business benefit. Except in the case of industrial physicians, entertainment of individuals who are not doctors will not ordinarily qualify because the possibility of benefits to be expected is so remote as to be negligible. In instances of the entertainment of patients, the same general rules apply as in the entertainment of other doctors, and the clear relationship of the expenditure to reasonably expected income must be shown. The same rules also apply to civic and other club dues.

Criteria to be used in establishing the deductibility of entertainment expenses include, but are not limited to, the following:

a. Specific purpose of entertainment. b. Nature of the practice of the doctor incurring the expenditure. c. Period of time the doctor has been in practice and the number of patients he already has. d. Percentage of his patients received as referrals. e. Names of individuals entertained and reason why additional income could reasonably be expected from each. f. Whether or not referrals were actually received from the doctors entertained and any indication of the effect of the entertainment on these referrals. g. Number of times individual doctors were entertained during the year, inasmuch as repeated entertainment indicates a personal motive. h. Whether or not other doctors in the same type practice in the locality have entertainment expenses.

We trust that the above will be helpful in clarifying this area of tax law and administration.

OPINIONS OF JUDICIAL COUNCIL

The Judicial Council has authorized the publication of the following opinions.

QUESTION: May I, as a patient's attending physician, discuss patient's history, diagnosis, treatment, prognosis, etc., with patient's attorney?

ANSWER: Yes, with the consent of the patient. The Principles of Medical Ethics recognize in Section 10 that the physician has obligations to society as a whole in addition to his obligations to his patient as an individual. In many instances, the peculiar knowledge and attainments of the physician are indispensable to patients or others in the administration of business and government and in the usual conduct of certain daily affairs. When this knowledge, acquired during the course of the physician-patient relationship, is necessary to enable the patient to obtain his just due the physician should make it available for patient's benefit under proper conditions. Discussion with or report to the patient's attorney may be proper and necessary in order for patient to perfect a claim. The attending physician may ethically discuss patient's history, etc. with the attorney providing, of course, patient has consented to the discussion.

QUESTION: We have just completed a new "medical arts" building to house a group of us who are practicing as individuals. We would like to have an "open house" for the public. Is this permissible?

ANSWER: Section 5 of the Principles proscribes the solicitation of patients. If the intent for having the "open house" is to solicit patients, even indirectly, then it would be contrary to the Principles. If, however, motivation for holding open house stems from civic and natural pride in having made a contribution to the community and to medicine then the practice may not be objectionable. In the latter instance, the holding of an open house might have the effect of acquainting the citizens of the community with some of the improvements developed for better patient care, comfort, and convenience. It might tend to convince the public that there is no apathy on the part of doctors when it comes to improving all facets of medical care.

Before a physician or a group of physicians hold such an open house, however, it is incumbent on him or them to discuss the proposal with appropriate officers of the component medical society. Communities and customs differ. The local society must assess local custom and usage and insure that neither the dignity of medicine nor local custom and tradition are offended by any particular practice of doctors.

QUESTION: What does the statement in Section 7 of the Principles mean when it says drugs, remedies, and appliances may be supplied by the physician provided it is in the best interest of the patient?

ANSWER: It is the opinion of the Judicial Council that this language was adopted to permit both the practicing physician and the local medical societies to evaluate the many factual situations incident to prescribing and dispensing which are bound to arise in the practice of medicine. Under this language the doctor is permitted to exercise his own best judgment when caring for his patients. It is known that there will be situations when it is necessary or desirable for a physician to dispense or supply what he has prescribed. The Principles permit this to be done. On the other hand, this broad language provides a means by which a component medical society can inquire into the facts of a particular practice. The profession thus can act to prevent abuse of discretion and protect patients from exploitation. In essence this language means that a physician in the exercise of sound discretion may dispense "in the best interest of his patient"; it does not authorize him to dispense solely for his convenience or for the purpose of supplementing his income.

QUESTION: Is it ethical to have another doctor perform surgery on my patient without patient's knowledge and consent?

ANSWER: No. The Principles in Section 2 state that the principal objective of the medical profession is to render service to humanity with full respect for the dignity of man. To have another physician operate on one's patient without that patient's consent, and without his knowledge of the substitution, is a fraud and deceit and a violation of a basic ethical concept. The patient as a human being is entitled to choose his own physician and he should be permitted to acquiesce in or refuse to accept the substitution.

A statement, prepared by the Law Department, is reproduced here as being educational on this matter.

> The surgeon's obligation to the patient requires him to perform the surgical operation: (1) within the scope of authority granted him by the consent to the operation; (2) in accordance with the terms of the contractual relationship; (3) with complete disclosure of all facts relevant to the need and the performance of the operation; and (4) to utilize his best skill in performing the operation.
>
> It should be noted that it is the operating surgeon to whom the patient grants his consent to perform the operation. The patient is entitled to the services of the particular surgeon with whom he contracts. The surgeon in accepting the patient obligates himself to utilize his personal talents in the performance of the operation to the extent required by the agreement, creating the physician-patient relation. He cannot properly delegate to another the duties which he is required to perform personally.
>
> Under the normal and customary arrangement with private patients, and with reference to the usual form of consent to operation, the surgeon is obligated to perform the operation himself, and he may use the services of assisting residents or other assisting surgeons to the extent that the operation reasonably requires the employment of such assistance. If a resident or other physician is to perform the operation under the guidance of the surgeon, it is necessary to make a full disclosure of this fact to the patient, and this should be evidenced by an appropriate statement contained in the consent.
>
> If the surgeon employed merely assists the resident or other physician in performing the operation, it is the resident or other physician who becomes the operating surgeon. If the patient is not informed as to the identity of the operating surgeon, the situation is "ghost surgery."
>
> An operating surgeon is construed to be a performing surgeon. As such his duties and responsibilities go beyond mere direction, supervision, guidance, or minor participation. He is not employed merely to supervise the operation. He is employed to perform the operation. He can properly utilize the services of an assistant to assist him in the performance of the operation. But he is not performing the operation where his active participation consists of guidance or standby responsibilities in the case of an emergency.

QUESTION: Is it ethical to disclose history, diagnosis, prognosis, etc., during the physician-patient relationship concerning my patient to an insurance company's representative?

ANSWER: Yes, if patient has consented to the disclosure. As recognized in Section 10 of the Principles a physician's responsibilities to his patient are not limited to the actual practice of medicine. They also include the performance of some services ancillary to the practice of medicine. These services might include certification that patient was under the physician's care and comment on the diagnosis and therapy in the particular case.

MEDICAL NEWS

ARKANSAS

Dr. Paul Day Goes with Food and Drug Administration.—The U. S. Commissioner of Food and Drugs, George P. Larrick, has announced the appointment of Paul L. Day, Ph.D., head, department of biochemistry and assistant dean, Graduate School, University of Arkansas School of Medicine, Little Rock, as scientific director of the U. S. Food and Drug Administration. Dr. Day who has been with the University of Arkansas School of Medicine for 31 years, is the author of many research papers in biochemistry and nutrition, a member of the Biochemistry Committee, National Board of Medical Examiners, and of numerous scientific societies, boards, and committees. He will assume his new position with the Food and Drug Administration sometime before the first of the year.

Personal.—Dr. Philip P. Ellis has been appointed associate professor to head the ophthalmology division in the department of surgery at the University of Arkansas Medical Center, Little Rock. Dr. Ellis formerly was assistant professor of ophthalmology at the State University of Iowa, Iowa City. The department has been awarded a $25,000 grant from the National Institutes of Health to be used toward paying salaries of personnel in the newly-created division.

CALIFORNIA

Personal.—Jacob Yerushalmy, Ph.D., professor of biostatistics, School of Public Health, University of California School of Medicine, Berkeley-San Francisco, has been appointed to the National Advisory Neurological Diseases and Blindness Council for a four-year term, the Surgeon General, U. S. Public Health Service, has announced.

COLORADO

Conference on Staphylococcal Disease.—A regional conference on the control of staphylococcal disease sponsored by the U. S. Public Health Service and Colorado State Department of Public Health was held in Denver, Oct. 15. Representatives from the Departments of Public Health of Wyoming, Utah, Montana, Idaho, and Colorado, Denver Department of Health and Hospitals, University of Colorado Medical Center, state medical societies in the Rocky Mountain Region, personnel from the Communicable Disease Center, Atlanta, hospital associations, Denver Medical Society, the Veterinary Medical School of Colorado State University, nursing associations, and many hospitals, participated. The forenoon was spent in sizing up the problem and the afternoon in working committees aimed at what to do to solve this problem.

CONNECTICUT

Personal.—Dr. Wilfred Bloomberg, of the Southern Regional Education Board staff, has accepted the post of commissioner of mental health for the state of Connecticut. He had been serving SREB temporarily as associate director for mental health. ——Dr. Seymour L. Lustman, formerly a clinical fellow in the Child Study Center, has been appointed associate professor in the department of psychiatry at Yale University School of Medicine, New Haven.——Dr. Denis Abelson, senior registrar and medical tutor at the Postgraduate Medical School in London, has been appointed assistant professor of preventive medicine at Yale University School of Medicine, New Haven. Dr. Abelson previously served at Yale as a research fellow in physiology.

DISTRICT OF COLUMBIA

Dr. Wolf to Head Department at Illinois.—The board of trustees of the University of Illinois College of Medicine, Chicago, has approved the appointment of Arnold V. Wolf, Ph.D., as head of the department of physiology at the College of Medicine, Chicago, effective Dec. 1. Dr. Wolf, presently chief, Renal Branch, Cardiovascular-Pulmonary Division, Walter Reed Army Institute of Research, will succeed Dr. George E. Wakerlin, who resigned to become medical director of the American Heart Association. Dr. Wolf for 10 years taught at Albany Medical College, New York. He is the author of many scientific publications and his book on the function of the kidney is said to be regarded as a classic. He is a charter member of the American Society for Artificial Internal Organs, and a member of the American Physiological Society and the American Association for the Advancement of Science.

ILLINOIS

Chicago

Alumni Seminar Day.—The University of Illinois Medical Alumni Seminar Day will be held Nov. 22 and all alumni of the College of Medicine are in-

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

vited. Speakers will include Dr. Granville A. Bennett, dean of the College of Medicine, and Dr. Carl A. Hedberg, president of the Medical Alumni Association. Two panel discussions are planned: "Blood Transfusions and Laboratory Aids in Diagnosis of Medicine Problems" and "Recent Advances in Surgery," which will be followed by question-and-answer periods. Seminars will be conducted in the afternoon by the departments of medicine, surgery, pediatrics, and obstetrics and gynecology. The medical seminar is co-sponsored by the College of Medicine and the Medical Alumni Association. Dr. Louis R. Limarzi, associate professor of medicine, is program chairman.

Personal.—Martin C. E. Hanke, Ph.D., associate professor of biochemistry at the University of Chicago, has been appointed director of the Clinical Chemistry Laboratory at the university's medical and biological research center.——Dr. Otto C. Koluvek and Dr. Samuel C. Udell have been elected to the Board of Trustees of the Chicago Medical School. Both men are alumni of the School.

INDIANA

Personal.—Dr. John L. Reck, of Sheridan, was honored recently with an open house and reception sponsored by Sheridan service clubs and merchants. He completed 50 years as a practicing physician in June. In 1955 Dr. Reck was the recipient of the first annual "Outstanding Citizen" award, given by the Sheridan Rotary Club.——Dr. Frank E. Wiedemann, Terre Haute, marked his 64th year of practice by cancelling all medical indebtedness on his books. He has done this several times in the past, the last time in 1956.

KANSAS

Society News.—New officers of the Kansas Society of Pathologists are: Dr. Leo P. Cawley, Wichita, president; Dr. Tom R. Hamilton, Kansas City, Kan., vice-president; Dr. William J. Reals, Wichita, secretary-treasurer and Councilor to the American Society of Clinical Pathologists; Dr. Richard F. Looker, Wichita, alternate councilor.

MARYLAND

Personal.—Dr. Isadore Kaplan has been named medical director of the Baltimore and Ohio Railroad Company, with system jurisdiction at Baltimore to succeed Dr. Samuel M. English, who retired July 1. Dr. Kaplan joined the B & O's medical department in January, 1946.——Dr. Russell A. Nelson, director of the Johns Hopkins Hospital, Baltimore, has been named president-elect of the American Hospital Association.

MASSACHUSETTS

Boston University Grants.—The Department of Health, Education and Welfare, has made the following grants: $30,186 to Dr. Henry J. Bakst, Brookline, professor of preventive medicine, Boston University School of Medicine, for program expansion in rehabilitation training in medicine. Brenton R. Lutz, Ph.D., Melrose, professor emeritus of biology, $22,982 to continue his research on the reaction of blood vessels to chronic high blood pressure. I. Alden Macchi, Ph.D., Newton Upper Falls, assistant professor of biology, $9,813 to continue his study of adrenal hormones. Walter J. Gensler, Ph.D., Belmont, professor of chemistry, $8,400 to investigate the possible use of an extract of tree resin in the treatment of cancer.

Personal.—Dr. Harry Blotner, Boston, has been appointed visiting research professor of science at Nasson College, Springvale, Maine.

MICHIGAN

"Visiting Chief Day" at Sinai Hospital.—At Sinai Hospital of Detroit on Nov. 5, the visiting Chief was Dr. Edward B. Solomons, professor of obstetrics and gynecology, State University of New York College of Medicine at New York City, Brooklyn, and formerly of Rotunda Hospital, Dublin, Ireland. The program consisted of a clinical conference at 10 a. m., and a motion picture and discussion on the Manchester operation at 1 p. m.

State Medical Election.—At the 93rd annual meeting of the Michigan State Medical Society in Detroit, held Oct. 4, the following new officers were elected: incoming president, Dr. Gilbert B. Saltonstall, of Charlevoix; president-elect, Dr. Milton A. Darling, of Detroit; speaker, Dr. Kenneth H. Johnson, of Lansing; and delegates to the American Medical Association for two-year terms, Drs. Wyman D. Barrett and Robert L. Novy, Detroit, and George W. Slagle, Battle Creek.

Michigan's Hearing Conservation Program.—In its 15th anniversary report on the state-local hearing conservation program, the Michigan Department of Health notes that group tests to find previously undetected cases of hearing loss have been given to 2,052,942 Michigan school children since 1943. In the present year the 60 locally employed technicians working in all parts of the state will screen about 350,000 children. Group technicians are paid by the school, local health departments, and other local organizations. The announcement said that of every 10,000 children given group screening, 50 to 75 are found to have losses that handicap or can't be corrected medically. The Michigan Department of

Health helps provide consultant services for children who may be given hearing aids, special training, or referred to the Michigan School for the Deaf, where they are taught how to use the hearing aid. The state, since 1947, has purchased 463 hearing aids for medically indigent children.

MINNESOTA

Personal.—Dr. Jurgen Aschoff, professor of physiology, Max Planck Institute at Heidelberg, Germany, conducted a seminar on "The Measurement of Blood Flow by Thermal Conductance" Sept. 19 at the Mayo Foundation, Rochester.——Dr. Howard B. Burchell, Rochester, has been appointed to the National Advisory Heart Council for a four-year term, the Surgeon General, U. S. Public Health Service, has announced.—Dr. Howard B. Burchell, professor of medicine in the Mayo Foundation, Graduate School, University of Minnesota, has been appointed to a 4-year term, beginning Oct. 1, as a member of the National Advisory Heart Council.——Dr. Archibald I. S. MacPherson, of the University of Edinburgh, Scotland, lectured at the Mayo Clinic, Rochester, October 13, on "Portal Hypertension and Its Treatment," and Dr. Joseph H. Boyes, of the University of Southern California School of Medicine at Los Angeles, conducted a seminar at the Clinic, October 10, on "Tendon Grafts in the Fingers and Thumb."

MONTANA

Society News.—At the annual meeting of the Montana Chapter of the American Academy of General Practice, Dr. Amos R. Little Jr., Helena, was elected president to succeed Dr. William E. Harris, Livingston. Dr. Philip D. Pallister, Boulder, was named vice-president and Dr. Harry R. Soltero, Billings, president-elect. Dr. Vernon D. Standish, Bigtimber, was re-elected secretary-treasurer.

NEVADA

Society News.—Officers of the American Academy of General Practice, Nevada Chapter, elected for 1958-1959 are: Drs. Robert V. Broadbent, Reno, president; Dennis Cunningham, Las Vegas, president-elect; and Richard C. Sheretz, Reno, secretary-treasurer. The 1959 meeting will be held in Reno in June and members of the staff of the Medical School of the University of Southern California, Los Angeles, will organize and present the program.

NEW YORK

The Harrington Lecture.—The University of Buffalo School of Medicine presented the Harrington Lecture Oct. 30. The lecturer was Dr. Robert A. McCance, professor of experimental medicine, University of Cambridge, England, whose subject was "Calories."

Dr. Hilleboe Honored.—The University of Buffalo School of Medicine on Oct. 18 awarded Dr. Herman E. Hilleboe, state health commissioner, a citation as "an outstanding protector of public health, both in America and abroad." The citation further read "we are particularly grateful to him for his interest and cooperation with the University of Buffalo School of Medicine, particularly for assistance in developing the Chronic Disease Research Institute and for his outstanding work with the Roswell Park Memorial Institute."

Personal.—Dr. Julius S. Prince, health officer of the Jamestown District Office, New York State Department of Health, is scheduled to leave this fall for a two-year tour of duty in Ethiopia as chief of the Health Division for the International Cooperation Administration.

New York City

Conference on Tuberculosis.—The Council of the Tuberculosis and Health Associations of Greater New York will hold a Conference on Tuberculosis: A World-Wide Problem, in the Biltmore Hotel Nov. 18, 3 p. m. Dr. Georges J. Canetti, chief of laboratories, Pasteur Institute, Paris, France, will speak on "Changes in the Nature of Tuberculosis from the Standpoint of Pathology"; Dr. Leona Baumgartner, New York City commissioner of health, on "Urban Reservoirs of Tuberculosis"; and Dr. Stig Johannes Holm, Geneva, Switzerland, chief, Tuberculosis Section, WHO, on "How Can Elimination of Tuberculosis as a Public Health Problem Be Achieved?"

Increase in Deaths from Tuberculosis.—The municipal health department reports that the number of deaths in the five boroughs of New York City during the year ending last June 30 was 1,021, an increase of 4.1% beyond that of the previous 12-month period. The largest increase, 11.3%, was in Manhattan. The increase in deaths in Brooklyn was 9.2% and in the Bronx 3%. In Richmond there was a decrease of 11.8% in deaths from tuberculosis. According to the New York Tuberculosis and Health Association, 6,233 new cases of tuberculosis were reported during the year mentioned. The municipal department of health was said to have records of 10,852 known cases of active tuberculosis in New York City.

Dr. Ochoa Honored.—At a reception at the New York University–Bellevue Medical Center Oct. 20, Dr. Severo B. Ochoa, chairman, department of biochemistry, was guest of honor. Dr. Ochoa received the Borden award during the annual meeting of the Association of American Medical Colleges in Philadelphia, Oct. 13. The award was based on his "isolation of the enzyme in crystalline form which catalyzes the condensation of oxaloacetic acid and acetyl coenzyme A to form citric acid and for his discovery and studies of polynucleotide phosphorylase." Dr. Ochoa, a graduate of the University of Madrid, Spain, has held faculty appointments at his alma mater; Oxford University Medical School, England; Kaiser-Wilhelm Institute for Medical Research, Heidelberg, Germany; and Washington University School of Medicine, St. Louis. He is a winner of the Neuberg Medal award in biochemistry, a past-president of the Harvey Society, and is a member of the National Academy of Sciences and the Council of the Society of Biological Chemists.

Affiliation of University and Institute.—New York University and the Institute for the Crippled and Disabled agreed on Sept. 25 to undertake joint efforts in rehabilitation research, teaching, and services to the handicapped. The documents of professional affiliation were signed before trustees and officers of the two institutions and distinguished guests, including Bernard Baruch, and Jeremiah Milbank, who founded the institute in 1917. The agreement, effective Nov. 1, among other things, is to provide all "types of service necessary for the handicapped to attain his fullest physical, social, and economic capability, and to undertake joint research into all areas of rehabilitation." The university and the institute will continue to function as financially independent, self-controlled institutions, and their rehabilitation activities will be coordinated through the university's recently created Center for Rehabilitation Services. The Institute for the Crippled and Disabled is an outpatient rehabilitation center whose services include medical treatment, social adjustment, and vocational training programs. It has facilities for making artificial limbs, a rehabilitation library said to be the largest of its kind, and it carries on research. The Institute will continue its joint efforts on specific projects with Columbia University, Presbyterian Hospital, and other institutions.

NORTH CAROLINA

Personal.—Dr. David R. Hawkins, associate professor of psychiatry, University of North Carolina School of Medicine, Chapel Hill, has been appointed a member of the Mental Health Small Grant Committee of the National Institute of Mental Health for a term of four years.——By direction of the Secretary of the Air Force, Dr. Herbert A. Saltzman, who is now on the faculty of Duke University School of Medicine, Durham, has been awarded the Air Force Commendation Medal.

OHIO

University News.—Studies of the relationships between speech and personality characteristics which have been carried on for three years in the University of Cincinnati College of Medicine department of psychiatry will be continued with a three-year grant of $50,000 made to Dr. Louis A. Gottschalk, associate professor of psychiatry. The grant was awarded by the U. S. Public Health Service, which also subsidized the previous years of research.

OREGON

Personal.—Dr. J. V. Straumfjord, of Astoria, has been appointed by Governor Holmes of Oregon to the State Board of Medical Examiners to fill the vacancy created by the death of Wilmot C. Foster. Dr. Straumfjord from 1929 to 1934 was on the staff of the University of Oregon Medical School and from 1930 to 1934 was a staff member of the Dr. Robert C. Coffey Clinic and Hospital. He has been engaged in private practice in Astoria since 1934.

PENNSYLVANIA

Bockus Society of Gastroenterology.—The Bockus International Society of Gastroenterology has been organized by alumni of the Graduate School of Medicine of the University of Pennsylvania. Dr. James L. D. Roth, secretary-general of the society and associate professor of gastroenterology, said the establishment of the group was accomplished under the impetus of Dr. Figueiredo Mendes, of Rio de Janeiro, Brazil, an alumnus of the school, who was elected president of the new society, with Dr. Jose Maria De La Vega, Mexico City, president-elect. Dr. Henry L. Bockus, chairman, department of internal medicine, University of Pennsylvania Graduate School of Medicine, was made honorary president. The group will study geographical differences in behavior patterns and epidemiology of diseases in different parts of the world. Its annual meeting will be held just prior to that of the American Gastroenterological Association or in accordance with the International Congress of Gastroenterologists. At the first annual meeting in Philadelphia, June 3, 1959, work groups will be organized to undertake collaborative research on projects to be reported on at future meetings.

Philadelphia

University News.—A Health Research Facilities Grant of $46,038 to The Woman's Medical College of Pennsylvania has been approved by the U. S. Public Health Service to purchase scientific equipment for the college's 2 million dollar Research Wing to be constructed this fall. The new six-story addition will provide space for an expanded Department of Physiological Chemistry and for the

Basic Science and Clinical Departments. A federal grant of one-half million dollars to help meet its construction costs was awarded to the college this spring.

TENNESSEE

University News.—A $95,000 grant to finance the study of the effects of exposure to relatively low amounts of radiation on bodily function has been awarded by the Surgeon General's Office, Department of the Army, to two investigators at the University of Tennessee College of Medicine. They are Richard R. Overman, Ph.D., director, Clinical Physiological Laboratories, and Dr. David S. Carroll, professor of radiology.

TEXAS

Personal.—Dr. William P. Wilson, assistant professor of psychiatry and neurology, Duke University, has been appointed director of psychiatric research and as professor of psychiatry and neurology, University of Texas Medical Branch, Galveston.—— D. Bailey Calvin, Ph.D., formerly Dean of Students and Curricular Affairs, University of Texas Medical Branch, Galveston, has been made Director of the Office of Research Grants and Contracts.

VERMONT

University News.—Dr. George A. Wolf Jr., University of Vermont College of Medicine, Burlington, has returned from Iran, where at the request of the University of Teheran Medical School he served as consultant, concerning the curriculum, under the auspices of the International Cooperation Administration.——Dr. John H. Bland, associate professor of medicine, has begun a year of study at the University of Manchester, England, with Prof. J. H. Kellgren, director of the Rheumatic Center there. ——William H. Macmillan, Ph.D., assistant professor of pharmacology, is on a year's leave of absence from the University of Vermont College of Medicine, working in the laboratory of Prof. J. H. Burn at the University of Oxford, England. Dr. Wilhelm Raab, professor of experimental medicine, has returned from a year's work in laboratories of the medical clinic of the University of Innsbruck, Austria.

VIRGINIA

Society News.—Dr. W. Linwood Ball, of Richmond, was installed as the twelfth president of the Virginia Academy of General Practice May 10. Other officers elected were: Dr. Fletcher J. Wright Jr., Petersburg, president-elect; Dr. William J. Hagood Jr., of Clover, vice-president; Dr. Russell G. McAllister and Dr. William A. Young, both of Richmond, reelected to serve as secretary and treasurer, respectively; Dr. John O. Boyd Jr., of Roanoke, reelected A. A. G. P. delegate; Dr. Rufus Brittain, of Tazewell, his alternate.

WASHINGTON

Dr. McDonald Goes to New York.—Dr. Ronald F. McDonald, head, division of urology, University of Washington School of Medicine, Seattle, has moved to Rochester, N. Y., where he has been appointed professor and head of the University of Rochester's division of urology. Dr. McDonald came to Seattle in 1949 from the University of Chicago.

GENERAL

Grants for Research in Leukemia.—The Leukemia Society, Inc., has announced the availability of grants-in-aid for research projects concerned with the cause or cure of leukemia and allied diseases. Applications, which may be made at any time, are reviewed by the Selection Committee quarterly: March, June, September, and December.

Medical Writers' Meeting in Philadelphia.—The 1958 fall meeting of the Delaware Valley Chapter of the American Medical Writers' Association will be held Nov. 17, 8:30 p. m., at the College of Physicians, Philadelphia. Rudolf Flesch, Ph.D., will present the Wyeth Lectureship, "The Right Way to Medical Writing," and also will review various medical journals. All persons interested in improving communication in medicine are invited. Fee for dinner at 6 p. m. for members and guests is $5.

Association of Blood Banks.—The 11th annual meeting of the American Association of Blood Banks will be in Cincinnati, Ohio, November 20-22. A scientific program will comprise individual papers, panels, and technical workshops throughout the meeting. The administrative section of the program also will include panel discussions. At the annual banquet Friday evening, the guest speaker will be Robert Dechert, Assistant Secretary of Defense, Washington, D. C.

Society News.—Dr. Edward B. D. Neuhauser of Boston was made president-elect of the American Roentgen Ray Society at the recent 59th annual meeting in Washington, D. C. Other officers elected were: Drs. Franklin B. Bogart, Chattanooga, Tenn., first vice-president; Arthur B. Soule, Jr., Burlington, Vt., second vice-president; C. Allen Good, Rochester, Minn., secretary; and Robert K. Arbuckle, Oakland, Calif., treasurer. The next annual meeting will be in Cincinnati, Ohio, September 21-25, 1959.

Scholarships for Neuromuscular Studies.—The Sister Elizabeth Kenny Foundation has announced continuation of its program of post-doctoral scholarships to promote work on neuromuscular diseases. Each grant will provide a stipend for five years at the rate of $5,000 to $7,000 a year, depending on the scholar's qualifications. Candidates from medical schools in the United States and Canada are eligible. Inquiries should be addressed to: Dr. Edgar J. Huenekens, medical director, Sister Elizabeth Kenny Foundation, Inc., 2400 Foshay Tower, Minneapolis 2, Minn.

Meeting on Psychoanalysis.—The Academy of Psychoanalysis held its mid-winter meeting at the Roosevelt Hotel, New York City, Nov. 6-7, under the presidency of Dr. Jules H. Masserman, of Chicago. The title for the Saturday morning session was "Psychoanalysis Today, Its Goals and Aspirations," on which subject Dr. George J. Mohr, clinical professor of psychiatry, University of Southern California School of Medicine, Los Angeles, presented an essay which was followed by a discussion in five individual presentations. On Sunday morning seven individual speakers were presented and their papers were discussed Sunday afternoon.

American Rheumatism Association.—The Fifth Interim Scientific Session of the American Rheumatism Association will be held December 6 at the Mayo Clinic, Rochester, Minn., under the presidency of Dr. Joseph J. Bunim. The general subjects of the sessions beginning Saturday, 9 a. m., will be immunologic studies, clinical studies, miscellaneous studies. Chairman of the program committee is Dr. James B. Wyngaarden, Durham, N. C. The vice-chairmen in charge of the Interim Session are Drs. Gene H. Stollerman, Chicago; Hans Waine, Boston, Mass.; and Morris Ziff, New York City. The address at the banquet in the Kahler Hotel will be presented by Dr. Philip S. Hench of Rochester on "Walter Reed and the Conquest of Yellow Fever."

Foreign Virologists Visit U. S.—Eight virologists from as many lands began a nine-weeks polio study course when they arrived at the Pan American Sanitary Bureau, Regional Office for the Americas of the World Health Organization, Oct. 2. All are studying "Polio Diagnostic Techniques, and Vaccine Production and Control" under WHO's fellowships program. The fellows come from U. S. S. R., Chile, Egypt, Nigeria, Poland, Lebanon, Austria, and French Equatorial Africa. Their itinerary includes training and observation at the Communicable Disease Center laboratories in Montgomery and Atlanta, and the Institute of Microbiology Polio Laboratory in Montreal as well as a visit to three pharmaceutical companies producing polio vaccine in Detroit and Indianapolis.

United Cerebral Palsy.—The annual scientific session of United Cerebral Palsy, 321 W. 44th St., New York 36, will be at the Mayflower Hotel, Washington, D. C., November 15. The morning session will be given over to eight papers and discussions on "The Problem of Hemiplegia—A Critical Evaluation," under the aegis of the clinical advisory committee. The afternoon session will be a continuation of discussions on the same general subject. The meeting is open without charge to physicians, medical students and other professional workers in related fields concerned with cerebral palsy. The president of United Cerebral Palsy is Roger S. Firestone, president of Firestone Plastics Company, and the executive vice-president, Stanley C. Hope, president of Esso Standard Oil Company.

Awards to Medical Periodicals.—At its September meeting in Chicago, the American Medical Writers' Association announced the 1958 honor awards for distinguished service in medical journalism to the following periodicals: *Cleveland Clinic Quarterly*, published by the Cleveland Clinic; *Harper Hospital Bulletin*, published by the Harper Hospital, Detroit; *The Bulletin of the Fulton County Medical Society*, Atlanta, Ga. (award for periodicals of county or city medical societies with a membership of 500 or more); *The Medical Record*, published by the Berks County Medical Society, Reading, Pa. (award for periodicals of county and city medical societies with a membership of less than 500). The awards are presented annually "for accuracy, clarity, conciseness and newness of information; for excellence of design, printing and illustrations."

Western Surgical Association.—The 66th annual meeting of the Western Surgical Association will be in Rochester, Minn., Nov. 20-22, with headquarters at the Hotel Kahler. At a pre-conference session Wednesday afternoon and evening, eight short papers will be presented by members of the Mayo Clinic staff. The clinico-pathologic conference will be at 7:30, and at 8:15 a regular meeting of the clinic staff especially arranged for this session. On Thursday beginning at 7:30 a. m. a chest conference will be followed by surgical clinics, and later surgical movies. In the afternoon 10 papers will be presented and on Friday 10 more and the presidential address by Dr. James B. Brown, St. Louis, on "Examples of the Inspiring Challenge to Medicine in Literature Through the Ages." Eight additional papers will be presented on Saturday.

Award for Essay on Thyroid Gland.—The American Goiter Association has again announced the offering of the Van Meter Prize Award of $300 and two honorable mentions for the best essays submitted concerning original work on problems related to the thyroid gland. The award will be made at the annual meeting of the association to be held in the Drake Hotel, Chicago, April 30-May 2, 1959. The competing essays may cover either clinical or research investigations, should not exceed 3,000 words, and must be in English. Duplicate typewritten copies, double spaced, should be sent to the Secretary, Dr. John C. McClintock, 149½ Washington Ave., Albany 10, N. Y., not later than Jan. 15, 1959. A place will be reserved on the program of the annual meeting for the presentation of the winning essay by the author.

Fellowships in Radiological Physics.—The Atomic Energy Commission is accepting applications for fellowships in radiological physics, which provide qualified graduate students with nine months of regular university graduate work in the sciences with three months of field training at an AEC installation. The assignments are made for study at Vanderbilt University, Nashville, Tenn., with field training at the Oak Ridge National Laboratory; at the University of Rochester (N. Y.) and Brookhaven National Laboratory; and at the University of Kansas, Kansas City, or the University of Washington, Seattle, and the Hanford Atomic Products Operation. The basic stipend is $2,500 a year plus $350 for each dependent. Tuition fees, and travel allowance are included under the fellowships. The Oak Ridge Institute of Nuclear Studies, P. O. Box 117, Oak Ridge, Tenn., administers these fellowships for the AEC. The deadline for appointments that will take effect the following fall is Jan. 2, 1959.

Society News.—The **American Association for the Study of Neoplastic Diseases** (the original Bloodgood group of Johns Hopkins Hospital, organized in 1930) at its meeting in Gatlinburg, Tenn., elected Dr. Victor Levine, Chicago, president, and Dr. William E. G. Bayley, Lafayette, Ind., vice-president. The next meeting also will be in Gatlinburg, April 30-May 4, 1959, to which all physicians interested in the study of tumors are invited. Microscopes are used during the sessions. Gatlinburg is the headquarters of the Great Smoky Mountains National Park.——At the annual meeting of the **American College of Gastroenterology**, Oct. 19, in New Orleans, Dr. Frank J. Borrelli of New York, president-elect, assumed the presidency and Dr. Joseph Shaiken, Milwaukee, Wis., was chosen as president-elect. Other officers elected were: vice-presidents, Drs. Henry Baker, Boston; Louis Ochs Jr., New Orleans; Edward J. Krol, Chicago; and Theodore S. Heineken, Glen Ridge, N. J.; and Dr. Joseph R. Van Dyne, Forest Hills, N. Y., secretary.

Meeting of Speech and Hearing Association.—The 34th annual convention of the American Speech and Hearing Association will be at the Hotel New Yorker, New York City, on November 17-19. Among the subjects of the sessions will be a symposium on "Recoveries from Aphasia," "Cerebral Palsy," "Stuttering," "Audiologic Evaluation of Middle Ear Surgery," "Current Research on Hearing Aids," "Organic Disorders Affecting Voice and Articulation," "Cleft Palate," "Language Development of the Deaf Child," and "Planning and Design of Modern Clinical and Research Facilities." There will be alumni luncheons, open house, cocktail hour and dance Tuesday evening, and scientific and commercial exhibits.

On November 20 at the Hotel New Yorker there will be a conference on "Research Needs in Speech Pathology and Audiology," sponsored by the American Speech and Hearing Association in cooperation with the U. S. Office of Vocational Rehabilitation and Veterans Administration.

Influenza on Okinawa and in Oregon.—In its Oct. 17 *Morbidity and Mortality Weekly Report*, the U. S. Public Health Service reported that the Division of Preventive Medicine, Bureau of Medicine and Surgery, U. S. Department of the Navy, had received information regarding the occurrence of influenza in military personnel stationed on Okinawa. The outbreak which occurred about the middle of September involved men of four different companies. In two companies 5 men each were ill; 12 in another, and 31 in the fourth company. The main complaints were fever, headache, and dizziness. A few had "chest colds" and headache. The men returned to duty by the fifth day. There were no complications. A virus was isolated which was reported to be closely related to and probably identical with the Jap/305 strain of influenza type A.

The Oregon State Board of Health reports that the incidence of influenza continues to increase. Some serologic evidence of influenza A infection has been obtained, but the type of virus has not been definitely identified as yet.

Academy of Dermatology and Syphilology.—The 17th annual meeting of the American Academy of Dermatology and Syphilology will be at the Palmer House, Chicago, December 6-11. The annual meeting will include, as in other years, special courses, symposiums, panels, informal discussion groups, luncheons, dinners, and executive sessions, and committee meetings. Among the special events will be the first of the James R. Webster Memorial Lectures honoring the late president of the academy who passed away while in office last February. The lecture on Sunday afternoon will be delivered by Dr. G. A. Grant Peterkin, of the University of Edinburgh, Scotland, whose subject will be "The Changing Pattern of Dermatology." The subjects of other special lectures will be radiation and cancer. Dr. Howard B. Latourette, Ann Arbor, Michigan, will discuss "Radiation Hazards" and Dr. Anthony Cipollaro, New York City, "Current Trends in Cutaneous Radiation Therapy." The Women's Hospitality Committee has arranged special activities for the ladies including a sight-seeing tour, climaxed by luncheon in Chinatown, and a fashion show at the Congress Hotel.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

LATIN AMERICA

Symposium on Cardiovascular Diseases.—An International Symposium on Cardiovascular Diseases will be held at Bogota, Colombia, South America, July 27-30, 1959, in which cardiologists from England, France, Sweden, Mexico, Cuba, and the United States will participate. The moderators of the several panels will be Drs. Adolfo De Francisco, Fernando Valencia, Alberto Castellanos, Jose Felix Patino, Alfonso Bonilla Naar, Miguel Trias, and Guillermo Rueda Montana. Among those from the United States scheduled to participate are Drs. Henry Swan II, Denver; John Maxwell Chamberlain, Mary Allen Engle, Charles E. Kossman, Joseph V. Brumlik, and Israel Steinberg, New York City; Richard J. Bing, St. Louis; Donald B. Effler, Cleveland; C. Walton Lillehei, Minneapolis; Michael E. DeBakey, Houston; Conrad R. Lam, Detroit; Dwight E. Harken, Robert E. Gross, and Alexander S. Nadas, Boston; Robert P. Glover, Philadelphia; Charles A. Hufnagel, Washington, D. C.; Francisco A. Hernandez, Miami; Frank L. Gerbode, San Francisco, and William W. L. Glenn, New Haven, Conn. Information may be obtained from Dr. Alberto Vejarano Laverde, Fundacion A. Shaio, Cra. 13, No. 43-23, Bogota, Colombia, South America.

CORRECTION

Medical Literature Abstracts.—In the paragraph on Medical Literature Abstracts on page 1040 of The Journal, Oct. 25, 1958 issue, the line which starts "Approximately two-thirds . . ." should have read "Approximately two-thirds of the abstracts from foreign literature are made from foreign language journals and one-third from publications of the British Commonwealth."

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Part II only, April 21-22; Parts I and II, June 16-17; Part I only, Sept. 9-10. Examinations must be received at least six weeks in advance of a specific examination date. Examining centers established after close of registration. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates, Inc.: Stations around the world, Feb. 17. Deadline for foreign applications is Nov. 17. The following examination will be held Sept. 22 with application deadline of June 22. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Written.* Montgomery, June 16-18. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery 4.

Arizona:* *Written Examination and Reciprocity.* Phoenix, Jan. 14-16. Sec., Dr. Thomas H. Bate, 2910 North 7th Ave., Phoenix.

Alaska:* On application in Anchorage and Juneau. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

California: *Oral Examination*, San Francisco, November 15. *Oral and Clinical Examination for Foreign Medical School Graduates.* San Francisco, June 15; Los Angeles, August 17; San Francisco, November 16. Sec., Dr. Louis E. Jones, 1020 N Street, Sacramento.

Colorado: *Written.* Denver, Dec. 9-10. Exec. Sec., Mrs. Beulah H. Hudgens, 715 Republic Bldg., Denver 2.

Connecticut:* *Homeopathic. Examination.* Derby, Jan. 13. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: *Written Examination and Endorsement.* Dover, Jan. 13-15, Jan. 22. Sec., Dr. Joseph S. McDaniel, Professional Bldg., Dover.

Florida:* *Examination.* Miami Beach, Nov. 23-25. Sec., Dr. Homer L. Pearson, 901 N. W. 17th St., Miami 36.

Georgia: *Examination and Reciprocity.* Atlanta, June. Sec., Mr. C. L. Clifton, 224 State Capitol, Atlanta 3.

Guam: *Subject to Call.* Act. Sec., Dr. F. L. Conklin, Agana.

Idaho: *Examination and Endorsement.* Boise, Jan. 12-14. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination and Reciprocity.* Chicago, Jan. 26-30. Supt. of Registration, Mr. Fredric B. Selcke, Capitol Bldg., Springfield.

Iowa:* *Examination and Endorsement.* Des Moines, Dec. 8-10. Exec. Sec., Mr. Ronald V. Saf, State Office Bldg., Des Moines 19.

Kentucky: *Examination.* Louisville, Dec. 8-10. Sec., Dr. Russell E. Teague, 620 South Third St., Louisville 2.

Maryland: *Examination.* Baltimore, Dec. 9-11. Sec., Dr. Frank K. Morris, 1211 Cathedral St., Baltimore 1.

Massachusetts: *Examination.* Boston, Jan. 13-16. Sec., Dr. Robert C. Cochrane, State House, Room 37, Boston 33.

Montana: *Examination and Reciprocity.* Helena, April 7. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

Nebraska:* *Examination.* Omaha, June. Director, Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

Nevada:* *Examination and Reciprocity.* Reno, Dec. 2. Sec., Dr. George H. Ross, 112 North Curry St., Carson City.

New Hampshire: *Examination and Endorsement.* Concord, Mar. 11-14. Sec., Dr. Edw. W. Colby, 61 So. State St., Concord.

New York: *Examination.* Albany, Buffalo, New York and Syracuse, Dec. 2-5. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

North Carolina: *Reciprocity.* Southern Pines, Jan. 17. *Examination.* June. Asst. Sec., Mrs. Louise J. McNeill, 716 Professional Bldg., Raleigh.

North Dakota: *Examination and Reciprocity.* Grand Forks, Jan. 7-10. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Examination.* Columbus, Dec. 16-18. *Endorsement.* Columbus, Dec. 16-18. Sec., Dr. H. M. Platter, Wyandotte Bldg., Columbus 15.

Oklahoma:* *Examination.* Oklahoma City, June 2-3. Exec. Sec., Mrs. E. L. Haidek, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Examination.* Portland, Jan. 6-7. *Reciprocity.* Portland, Jan. 8-10. Exec. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland 4.

Pennsylvania: *Endorsement.* Harrisburg, Dec. 11-12. *Examination.* Philadelphia, Jan. 7-10. Sec., Mrs. Margaret G. Steiner, Box 911, Harrisburg.

Rhode Island:* *Examination.* Providence, Jan. 8-9. Admin., Division of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Endorsement.* Columbia, Dec. 9. Sec., Dr. H. E. Jervey, Jr., Blanding Bldg., Columbia.

South Dakota:* *Examination.* Sioux Falls, Jan. 20-21. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:* *Examination.* Memphis, Dec. 17-18. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Texas:* *Examination and Reciprocity.* Fort Worth, Dec. 4-6. Sec., Dr. M. H. Crabb, 1714 Medical Arts Building, Fort Worth 2.

Utah: *Examination.* Salt Lake City, July 8-10. Dir., Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

Virginia: *Examination and Reciprocity.* Richmond, Dec. 4-6. Address: Virginia Board of Medical Examiners, 631 First St., S. W., Roanoke.

Washington:* *Examination.* Seattle, Jan. 12-14. Sec., Mr. Thomas A. Carter, Capitol Bldg., Olympia.

West Virginia: *Examination and Reciprocity.* Charleston, Jan. 5-7. Sec., Dr. Newman H. Dyer, State Office Bldg. No. 3, Charleston 5.

Wisconsin:* *Examination and Reciprocity.* Madison, Jan. 13-15. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., 1 West Wilson St., Madison.

Wyoming: *Examination and Reciprocity.* Cheyenne, Feb. 2. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: *Examination.* Tucson, Dec. 16. Sec., Mr. Herman E. Bateman, University of Arizona, Tucson.

Colorado: *Examination and Reciprocity.* Denver, Dec. 3-4. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

Connecticut: *Examination.* New Haven, Feb. 14. Exec. Asst., Mrs. Regina G. Brown, 258 Bradley St., New Haven 10.

Florida: *Examination.* Miami, June 6. Sec., Mr. M. W. Emmel, University of Florida, Box 340, Gainesville.

Iowa: *Examination.* Des Moines, Jan. 13. Sec., Dr. Elmer W. Hertel, Wartburg College, Waverly.

Kansas: *Endorsement.* Kansas City, Jan. 14. *Examination.* Kansas City, Jan. 16-17. Sec., State Board of Healing Arts, Dr. F. J. Nash, New Brotherhood Bldg., Kansas City.

Michigan: *Examination.* Ann Arbor and Detroit, Feb. 12-13. Sec., Mrs. Anne Baker, 116 Stevens T. Mason Bldg., West Michigan Ave., Lansing.

Minnesota: *Examination.* Minneapolis, Jan. 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.

New Mexico: *Examination.* Santa Fe, Jan. 18. Sec., Mrs. Marguerite Cantrell, Box 1522, Santa Fe.

Oklahoma: *Examination.* Oklahoma City, Mar. 27-28. Exec. Sec., Mrs. L. Haidek, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, Dec. 6. Sec., Dr. Earl M. Pallett, Box 5175, Eugene.

Rhode Island: *Examination.* Providence, Nov. 19. Admin. of Professional Regulation, 366 State Office Bldg., Providence.

South Dakota: *Examination.* Vermillion, Dec. 5-6. Sec., Dr. Gregg M. Evans, 310 East 15th St., Yankton.

Tennessee: *Examination.* Memphis, Dec. 31-Jan. 1. Sec., Dr. O. W. Hyman, 62 South Dunlap St., Memphis 3.

Texas: *Examination.* April 1959. Certificates issued by reciprocity and waiver on the first and fifteenth of each month. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Washington: *Examination.* Seattle, Jan. 7-8. Sec., Mr. Thomas A. Carter, Capitol Bldg., Olympia.

Wisconsin: *Examination.* Milwaukee, Dec. 6, Madison, Apr. 4. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

*Basic Science Certificate required.

DEATHS

Auerbach, Julius Ⓜ Chicago; Chicago College of Medicine and Surgery, 1913; on the staff of the Walther Memorial Hospital; died while on a vacation in Sturgeon Bay, Wis., Sept. 27, aged 75.

Baldwin, Janet Sterling Ⓜ New York City; born in Lakewood, N. J., June 4, 1908; Johns Hopkins University School of Medicine, Baltimore, 1935; certified by the National Board of Medical Examiners; specialist certified by the American Board of Pediatrics; member of the American Pediatric Society and the American Academy of Pediatrics; associate professor of pediatrics at the New York University College of Medicine; member of the board of directors of the New York Heart Association; associated with the University, Bellevue, and Lenox Hill hospitals; died in the Presbyterian Hospital Sept. 17, aged 50, of cancer of the thyroid with cervical metastases.

Bender, Alva Jacob Ⓜ Salida, Colo.; Rush Medical College, Chicago, 1909; served on the faculty of his alma mater; a member of the board of education and county health officer; veteran of World War I; formerly on the staff of the Denver and Rio Grande Western Hospital, where he died Aug. 29, aged 83.

Bland, James Moncure, Boykins, Va.; Medical College of Virginia, Richmond, 1905; chairman of the Southampton County Board of Supervisors; killed Sept. 11, aged 76, in an automobile accident.

Bonnell, George Harrison Ⓜ Worthington, Ohio; Starling Medical College, Columbus, 1906; for many years member of the school board of which he was past-president; died Sept. 12, aged 77, of pulmonary emphysema.

Brown, William Lee Sr. Ⓜ Tucson, Ariz.; Rush Medical College, Chicago, 1916; formerly practiced in Chicago where he was associated with St. Luke's and Chicago Memorial hospitals; member of the Illinois State Medical Society; specialist certified by the American Board of Radiology; veteran of World War I; died in St. Mary's Hospital Sept. 10, aged 70.

Bullock, Norman Charles, La Jolla, Calif.; University of Illinois College of Medicine, Chicago, 1927; formerly practiced in Rockford, Ill., where he was health commissioner, past-president of the Winnebago County (Ill.) Medical Society and president of the board of trustees of the Rockford Municipal Tuberculosis Sanatorium; veteran of World War II; a member of the county health department; died in San Diego Aug. 31, aged 58, of pulmonary emphysema and cor pulmonale.

Burton, William Stone, Louisville, Ky.; Medical College of Virginia, Richmond, 1937; served as medical superintendent of the District Six Tuberculosis Hospital in Glasgow and on the staff of the W. T. Edwards Tuberculosis Hospital in Tallahassee, Fla.; consultant at the Hazlewood Sanatorium; died Aug. 15, aged 44, of cancer.

Crotty, Nora Ⓜ Cincinnati; Cincinnati College of Medicine and Surgery, 1902; four times elected vice-president of the Cincinnati Academy of Medicine; died Sept. 14, aged 88.

Davidson, Walter E. Ⓜ Liberty, Ill.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1901; served as a member of the board of health of Adams County; died in the Blessing Hospital, Quincy, Sept. 2, aged 82.

Davis, William T. Ⓜ Scranton, Pa.; Medico-Chirurgical College of Philadelphia, 1911; past-president and secretary of the Lackawanna County Medical Society; served on the staff of the American Red Cross; formerly health director of Lackawanna County; at one time chief medical officer of the Lackawanna Railroad; formerly chief of medical service at Moses Taylor Hospital, where he died Sept. 23, aged 73.

Dillen, Oscar Marion, Lufkin, Texas; University of Tennessee College of Medicine, Memphis, 1915; veteran of World War I; on the staff of the Memorial Hospital and Angelina County Hospital, died Sept. 4, aged 72, of cerebrovascular accident.

Ferree, Arthur Cruzon Ⓜ Buena Park, Calif.; University of California School of Medicine, San Francisco, 1943; member of the American Academy of General Practice; veteran of World War II and served in France and Germany with the 6th Army as a battalion surgeon winning the Bronze Star for gallantry in directing evacuation of 275th Infantry wounded under fire; served on the staffs of St. Jude Hospital in Fullerton, St. Joseph Hospital in Orange, Santa Ana (Calif.) Community Hospital, Whittier Memorial and Carobil Hospital at Norwalk; died Sept. 4, aged 40, of myocardial infarction.

Finsterwald, Charles Frederick, San Antonio, Texas; Ohio State University College of Medicine, Columbus, 1916; died in Naples, Fla., July 28, aged 73, of coronary occlusion.

Ⓜ Indicates Member of the American Medical Association.

Fort, Chester Arthur Jr. Ⓜ Jacksonville, Fla.; born in Ocala, Oct. 11, 1910; Tulane University School of Medicine, New Orleans, 1936; specialist certified by the American Board of Urology; member of the Southeastern Surgical Congress and the American Urological Association; fellow of the American College of Surgeons; formerly on the faculty of Emory University School of Medicine in Atlanta, Ga.; served during World War II; on the staffs of St. Vincent's, St. Luke's, Riverside and Brewster hospitals, and Duval Medical Center; died near Melrose Sept. 1, aged 47, while on a fishing trip.

Fulton, James Fairfax, Staunton, Va.; Medical College of Virginia, Richmond, 1919; member of the American Psychiatric Association; served as health officer; chief of the male service, Western State Hospital; died in the King's Daughters Hospital Sept. 5, aged 64, of myocardial infarction.

Galloway, Philip Lee, Glendale, Calif.; University of Kansas School of Medicine, Kansas City, 1944; veteran of World War II; on the staff of the Queen of Angels Hospital, Los Angeles; died Sept. 7, aged 38, of a heart attack.

Gazzolo, Louis Joseph Ⓜ Chicago; Chicago Medical School, 1945; member of the Industrial Medical Association; formerly health officer with the Chicago Board of Health; veteran of the Korean War; associated with the Lewis A. Weiss Memorial Hospital and the Michael Reese Hospital, where he died Sept. 17, aged 45, of acute myocardial infarction.

Gilbert, William Paul Ⓜ San Francisco; College of Medical Evangelists, Loma Linda and Los Angeles, 1937; certified by the National Board of Examiners; member of the American Academy of General Practice; died in the Mount Zion Hospital Aug. 7, aged 55, of coronary occlusion.

Graves, John William Ⓜ Indianapolis; Indiana University School of Medicine, Indianapolis, 1927; veteran of World War II; for many years on the faculty of Indiana University School of Dentistry and taught for two years at the Indiana College of Mortuary Science; author of textbooks and laboratory manuals; died Sept. 6, aged 57.

Gunn, William Ussery, Clinton, S. C.; University of Louisville (Ky.) School of Medicine, 1949; clinical director at Whitten Village; died in the Self Memorial Hospital, Greenwood Sept. 16, aged 38, of atelectasis of lungs and bilateral and bronchopneumonia.

Hackler, John Fielden Ⓜ Muskogee, Okla.; born in Tahlequah, Dec. 11, 1910; University of Oklahoma School of Medicine, Oklahoma City, 1933; specialist certified by the American Board of Preventive Medicine; entered the public health field Sept. 1, 1936 as director of the Payne County Health Department in Stillwater, Okla.; in 1940 became director of the field advisory staff of the Oklahoma State Board of Health, serving until 1943, and for 12 years served as chairman of the records committee; visiting lecturer in preventive medicine and public health and first full-time chairman and professor of preventive medicine and public health at his alma mater from 1943 to 1948, when he was appointed director of the city-county health unit; served as secretary of the Payne County Medical Society; charter member of the American Association of Public Health Physicians; was a member of the board of directors of the Oklahoma division of the American Cancer Society; for several years on the board of directors of the Oklahoma Congress of Parents and Teachers, serving as chairman of community health; author of articles in the field of preventive medicine and public health; died Sept. 3, aged 47, of rheumatic heart disease with aortic insufficiency and mitral stenosis.

Haines, Harold Grunder Ⓜ Berlin, Pa.; University of Pittsburgh School of Medicine, 1920; associated with Somerset (Pa.) Community Hospital; president of the Berlin Lions Club; died Sept. 16, aged 63, of third degree burns received in a fire following an explosion in his home.

Hanson, Charles Joseph, Easthampton, Mass.; Baltimore Medical College, 1904; served as school physician, a member of the school committee, medical examiner for the Second Hampshire District, and as agent of the board of health; health officer of Easthampton; died in the Cooley Dickinson Hospital, Northampton, Aug. 31,aged 76.

Jennings, Edward Allen, New York City; Columbia University College of Physicians and Surgeons, New York City, 1913; member of the Medical Society of the State of New York; served on the staffs of the Harlem, Fordham, and St. Luke's hospitals; died Sept. 10, aged 76, of cerebral hemorrhage.

Kaplan, Murray M., Boston; Eastern University School of Medicine, Baltimore, 1913; died Sept. 5, aged 68.

Kiebala, Joseph Kasmer, Buffalo; University of Buffalo School of Medicine, 1913; member of the Medical Society of the State of New York; died Sept. 1, aged 66.

Lusher, Homer Virgil Ⓜ Huntington, W. Va.; Medical College of Ohio, Cincinnati, 1906; died Sept. 12, aged 76.

McCandless, Orville Calnon Ⓜ Cheyenne, Wyo.; Washington University School of Medicine, St. Louis, 1925; veteran of World War I; Laramie county health officer; served as health officer of Marion County, Kan.; died in the Veterans' Administration Hospital Sept. 12, aged 63, of coronary thrombosis.

McClure, Charles Richard Ⓜ Portland, Ore.; Medical College of Ohio, Cincinnati, 1901; professor emeritus of orthopedic surgery at the University of Oregon Medical School; member of the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; for many years served as examiner for the Oregon Industrial Accident Commission; served on the staffs of the Doernbecher Memorial Hospital for Children, Multnomah County Hospital, and Shriners' Hospital for Crippled Children; died Sept. 4, aged 81.

McMeans, Joseph William Ⓜ Anderson, S. C.; born in Toledo, Ohio, Jan. 25, 1891; University of Pittsburgh School of Medicine, 1912; specialist certified by the American Board of Pathology; member of the American Association of Pathologists and Bacteriologists, College of American Pathologists, and the American Society of Clinical Pathologists; fellow of the American College of Physicians; for many years practiced in Pittsburgh, where he was chief coroner's pathologist in Allegheny County, and served on the staff of Pittsburgh Hospital; formerly pathologist at the Allegheny Valley Hospital in Tarentum; pathologist at Anderson Memorial Hospital; died Sept. 2, aged 67, of dissecting aneurysm of the aorta.

Maley, Thomas Francis Ⓜ Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1924; died Sept. 12, aged 60.

Martin, James Jackson, Dawson, Ga.; Atlanta College of Physicians and Surgeons, 1913; an associate member of the American Medical Association; veteran of World War I; died in the Patterson Hospital, Cuthbert, Aug. 30, aged 68.

Mintz, Maurice Emanuel, New York City; University and Bellevue Hospital Medical College, New York City, 1909; member of the Medical Society of the State of New York; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; on the staffs of the Mount Sinai Hospital and Sydenham Hospital; died Sept. 10, aged 72.

Murdoch, James Wilson Ⓜ Chapel Hill, N. C.; University of Aberdeen Faculty of Medicine, Scotland, 1924; member of the American Psychiatric Association; served as medical superintendent of the North Carolina State Hospital in Butner; died in the Memorial Hospital Sept. 16, aged 58, of cerebral hemorrhage and hypertensive cardiovascular disease.

Myers, Roy Everett Ⓜ Joplin, Mo.; National University of Arts and Sciences Medical Department, St. Louis, 1916; past-president of the Jasper County Medical Society; associated with Freeman Hospital and St. John's Hospital, where he died Sept. 4, aged 68, of coronary disease.

Nevitt, Orme Richardson Ⓜ Raymond, Wash.; born in 1878; University of Minnesota College of Medicine and Surgery, Minneapolis, 1900; member of the American Academy of General Practice; past-president of the Pacific County Medical Society; helped organize the Pacific County Tuberculosis League of which he was president; served as health officer; in 1951 was named "Washington General Practitioner of the Year" by the state medical association; associated with the work of the American Red Cross for more than 50 years, serving many terms as county chapter chairman and was chairman emeritus at the time of his death; district registrar of vital statistics for many years; the Nevitt Memorial swimming pool, was built and dedicated in honor of his service to Raymond and the surrounding community; on the staff of the Willapa Harbor Hospital in South Bend, where he died Sept. 6, aged 79, of cancer.

Olms, Frank Albert, St. Petersburg, Fla.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1895; for many years practiced in Hampshire, Ill.; served on the staffs of the St. Joseph and Sherman hospitals in Elgin, Ill.; died Sept. 6, aged 83, of heart disease and pneumonia.

Pence, James William, Columbus Junction, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1907; served as medical examiner for the Rock Island Railroad; from 1941 to 1947 medical examiner for the Louisa County Draft Board; served as county coroner; died in the Bellevue Hospital, Muscatine, Aug. 30, aged 79, of diabetes mellitus.

Predmore, Donald Ford, Montrose, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1934; died Sept. 5, aged 50.

Prevor, Morris Aaron, Brooklyn; St. Louis University School of Medicine, 1929; member of the Medical Society of the State of New York; died in the Brooklyn State Hospital Aug. 14, aged 54, of cerebrovascular accident and arteriosclerosis.

Quattlebaum, Theodore Adolphus, Winnsboro, S. C.; Vanderbilt University School of Medicine, Nashville, Tenn., 1899; served as superintendent of the Carolina Orphan Home, Columbia, and the Croswell Home in Sumter; died in the Baptist Hospital, Columbia, Aug. 24, aged 82.

Reitz, Charles, Rochester, N. Y.; Bellevue Hospital Medical College, New York City, 1890; an associate member of the American Medical Association; on the staff of the Park Avenue Hospital; died Sept. 3, aged 91, of coronary occlusion.

Riley, James Horatio, Westport, Conn.; Starling-Ohio Medical College, Columbus, 1912; member of the Ohio State Medical Association; veteran of World War I; served on the staffs of the Mercy and Springfield hospitals in Springfield, Ohio; died in Norwalk, Conn., Sept. 7, aged 69, of cerebral hemorrhage.

Schnaer, Carl Henry, Chicago; Chicago College of Medicine and Surgery, 1916; served on the staffs of the German Evangelical Deaconess Hospital and Englewood Hospital; died in the Veterans Administration Research Hospital Sept. 24, aged 73, of heart disease.

Schwarz, Francis Stenard Jr., Ⓜ Cleveland; Cornell University Medical College, New York City, 1943; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; formerly associated with the U. S. Public Health Service; on the staffs of the St. Vincent Charity and St. Luke's hospitals; died in Medina, Ohio, Aug. 31, aged 37, of injuries received in an automobile accident.

Sewell, Harry Dickey, Rochester, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1909; an associate member of the American Medical Association; fellow of the American College of Physicians; associated with the Veterans Administration; formerly member of the medical division of Eastman Kodak Company; died in the Veterans Administration Hospital, Boston, Aug. 25, aged 75, of cancer.

Sherer, William Walter, Los Angeles; University of Southern California College of Medicine, Los Angeles, 1906; died in the Parkview Hospital Aug. 29, aged 79, of cancer of the pancreas.

Shirk, Paul Kuhlmann, Watervliet, N. Y.; Jefferson Medical College of Philadelphia, 1930; formerly practiced in Yonkers, where he was on the staff of the St. John's Riverside Hospital; medical rating specialist and personnel physician at the Veterans Administration office at the Watervliet Arsenal; died Aug. 27, aged 64.

Soucek, Adolph Ⓜ Madison, Wis.; State University of Iowa College of Medicine, Iowa City, 1931; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; served as assistant physician at the State Hospital and School, Woodward, Iowa, assistant superintendent of the Cherokee (Iowa) State Hospital, superintendent of the Mount Pleasant (Iowa) State Hospital, and assistant superintendent of the Mendota State Hospital; died Aug. 30, aged 51, of cryptococcosis.

Spain, A. L., Ⓜ Letona, Ark. (licensed in Arkansas in 1903); died Aug. 23, aged 85.

Spratt, John Thomas Ⓜ Mingus, Texas; Dallas Medical College, 1902; for many years surgeon for the Texas and Pacific Railway; died in Strawn (Texas) Hospital Sept. 3, aged 83, of third degree burns received while burning trash.

Stahl, Clare William, Topeka, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1904; veteran of the Spanish-American War; died Aug. 31, aged 80, of cancer of the esophagus.

Styles, George Wilson, Miami, Fla.; Meharry Medical College, Nashville, Tenn., 1948; died June 4, aged 45, of cerebral hemorrhage, hypertension and arteriosclerosis.

Terflinger, Fred Weston Ⓜ Logansport, Ind.; Medical College of Indiana, Indianapolis, 1902; veteran of World War I; served as superintendent of the Logansport State Hospital; a charter member and past-president of the Rotary Club; died in St. Joseph's Hospital Sept. 5, aged 84.

Treible, William Henry, St. Petersburg, Fla.; Jefferson Medical College of Philadelphia, 1896; an associate member of the American Medical Association; formerly practiced in York, Pa., where he was associated with the York Hospital; died Aug. 22, aged 92, of cerebral thrombosis.

Welsh, Arthur Brinkley Ⓜ Colonel, U. S. Army, retired, Newton Square, Pa.; University of Pittsburgh School of Medicine, 1925; entered the medical corps of the U. S. Army July 12, 1926, and retired Oct. 31, 1954; awarded the Legion of Merit for conspicuous and meritorious service in the Army from November 1941 to May 1945; service member of the American Medical Association; died in Harrisburg Sept. 4, aged 57, of coronary occlusion.

Westrope, Gordon Robert Ⓜ Columbia, S. C.; Medical College of South Carolina, Charleston, 1927; member of the American Psychiatric Association; veteran of World War I; formerly practiced in Gaffney, and served as district health director and director of the Cherokee County Health Department; for many years associated with the South Carolina State Hospital; died Aug. 25, aged 65.

Williams, Edwin Lacy, Fort Meade, Fla.; Atlanta College of Physicians and Surgeons, 1904; died June 1, aged 85, of arteriosclerotic heart disease and hypertension.

Williams, Paul Sinclair, Santa Cruz, Calif.; Western Reserve University School of Medicine, Cleveland, 1931; died Aug. 27, aged 52.

Wilson, Claude Ⓜ Greenville, Ky.; University of Louisville (Ky.) Medical Department, 1910; veteran of World War I; on the staff of the Muhlenburg Community Hospital; died Aug. 21, aged 78.

Zachariah, Simon R., San Francisco; College of Physicians and Surgeons, San Francisco, 1900; served with the British Army during World War I; died Sept. 7, aged 80.

FOREIGN LETTERS

INDIA

Scurvy.—A. Chakravarty and co-workers (*Indian J. Child Health* 7:8 [Aug.] 1958) stated that while protein malnutrition, rickets, hypovitaminosis A and B, and anemia are common, the incidence of scurvy in India is believed to be low, but they observed 28 cases of scurvy in a period of 17 months. The number of patients diagnosed as having scurvy was much larger, but the diagnosis could not be confirmed because these patients were lost sight of. Most were boys, with the preponderance being between the ages 2 and 3 years, and the largest number of patients were seen between October and January. Most of them came from poor families, and their diet was deficient in calories and vitamins. The diet contained an insignificant quantity of pulses and milk, while fruits were uniformly absent. A history of a preceding illness was available in 21 patients, the most common being fever of undetermined origin and upper respiratory tract infection. The onset was acute in 24 and insidious in four.

The common clinical findings were tenderness over the lower limbs and pseudoparalysis with inability to bear weight. In eight the tenderness was severe enough to make the child cry when the limbs were touched. Pseudoparalysis was unilateral in nine. Most of the children were irritable. Mild to moderate anemia was present in almost all patients, but frank bleeding from the gums was found in only five. One girl of 6 years came to the hospital with generalized hemorrhages and pseudoparalysis, rapidly developed coma, and died, probably of a subarachnoid hemorrhage. There were no other deaths. Seven showed evidence of multiple vitamin deficiencies. A mild polymorphonuclear leukocytosis was seen in 14. Bone marrow biopsy was done in seven patients; six of these had a normoblastic and one a megaloblastic appearance. The Kahn test was done in two of those below the age of 2 years to rule out congenital syphilis and was found to be negative.

Radiologically, the commonest sign was the white line of Fränkel, associated with a zone of rarefaction below it. One patient had subperiosteal calcification. During the process of healing the Trummerfield's zone of rarefaction was the first to disappear, trabeculas appeared, and the effusion in the joints gradually diminished. The vitamin C content of the blood was estimated, and it was noticed that those with a content of less than 0.1 mg. per 100 ml. had frank hemorrhages. The highest level of vitamin C in the blood associated with the presence of bleeding gums was 0.22 mg. per 100 ml. In 18 a close correlation between the blood level of vitamin C and the severity of symptoms was noted. These patients were given 200 to 500 mg. of vitamin C daily by mouth, the dose depending on the severity of the condition. Diminution in tenderness, pain, and irritability was noticed within 72 hours, and full return to normal weight bearing was possible in early cases after 7 to 14 days of treatment. Two patients responded very slowly to therapy. The blood vitamin C level took about two weeks to show a rise and returned to normal within 3 to 12 weeks.

NEW ZEALAND

Van Meter Prize.—Dr. Duncan D. Adams has been awarded the American Goiter Association's Van Meter prize. This prize is given annually for the best research on the thyroid gland anywhere in the world. Dr. Adams is on the staff of the endocrinology research unit of the New Zealand Medical Research Council. He gained the prize for his work in connection with toxic goiter. In collaboration with Dr. H. D. Purves he developed a method of detecting and measuring thyroid-stimulating hormones. Application of this method led to the discovery that patients suffering from the disease have an abnormal thyroid-stimulating hormone in their blood. The discovery has since been confirmed by American scientists. It has led to a new line of investigation which promised to reveal the basic cause of the disease.

Health Service Reviewed.—Dr. J. P. S. Jamieson (*Brit. M. J.* [supp.] 2:15 [July 5] 1958) reported that to understand the social security medical services in New Zealand it is necessary to review the system which existed before their introduction. Public hospitals, financed by local taxes, government subsidy, patients' fees, and voluntary contributions, and administered by local boards, served all parts. Most wage earners paid for themselves. The poor were assisted by hospital boards and relied largely on the benevolent services of the doctors. During the depression of the 1930's, it became evident that a greater participation by the state in health matters was inevitable. A committee was set up to examine the needs of the country and to in-

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

quire into the systems of other countries. The committee advised (1) a gradual introduction of the service and emphasized prevention of and research on diseases, (2) greater access to x-ray examination, laboratory and pathological investigation, and other costly procedures, (3) free service for those unable to pay for medical care, the cost to be borne by the state, (4) reduced costs for maternity care and hospitalization, and (5) insurance of those with smaller incomes against sickness in the home on a contributory-subsidized basis.

The government, however, inclined toward a universal revolutionary system, by which, in keeping with the ideology of state ownership and control, all medical service would be entirely under the government and all physicians would become virtually state employees. After various unacceptable proposals by the government, the New Zealand Branch of the British Medical Association considered a fee-for-service system at $1.10 for consultation or visit and $2 for consultation or visit at night and on Sundays and holidays and mileage for country visits. During World War II this became law. The branch saw in this the danger of the state interposing between patient and doctor and ultimate domination of the profession. At this point, the Prime Minister intervened with the proposal of an alternative to the fee-for-service claim on the fund by the general practitioner. He suggested that those who preferred might charge the patient himself such fees as he thought fit, and the patient could obtain, on presentation of his receipted account, a refund equal to the fee-for-service payment. By this method the state did not come between physician and patient, the patient-doctor relationship was preserved, and the physician would not be in any sense a government servant in his practice.

Provision was also made on a salary basis for the service of certain small isolated communities and for people living in scattered districts in which a physician ordinarily could not make a living. There are specialists on the staff of the free hospitals, and the patients of private specialists get the ordinary refund on their accounts for each attendance. Later, radiological, diagnostic, laboratory, and pathological services were established. Briefly, medical services are now available "free" to everyone from birth till death—"free," but paid for by taxation. The cost of the general practitioner, however, absorbs but a fraction more than 12 of the 18 cents social security tax. Medical service is efficient. People are living longer. Maternal mortality is one of the lowest in the world. Neonatal deaths have diminished. Rehabilitation for invalidism is quicker than it used to be. Doctors are fully employed and can practice wherever they choose. There are some weaknesses in the system; there is undue reference of patients to hospital for things the physician should do for himself; there is waste of drugs; and in some cases there is a tendency to exploit the fund by overattendance; but on the whole it is satisfactory.

NORWAY

Causes of Death.—When a woman of 70 with a history of rheumatic fever in childhood, angina pectoris in later years, and a possible infarct is found on examination to present a systolic murmur over the apex, a bundle-branch block on an electrocardiographic examination, marked systolic and diastolic hypertension, chronic bronchitis, and emphysema, how is her death certificate to be worded? With this and kindred problems in his mind, Prof. H. J. Ustvedt (*Tidsskrift for den norske lægeforening*, Sept. 1, 1958) set the staff of his side of Ullevaal Hospital the task of analyzing, in terms of death certificates, records of the 118 patients discharged in June, 1957. Half of this number were over the age of 60, and only 10% were under 40. None was under 20. Each of five members of his staff listed these patient's ailments independently of each other. In only 18 cases did they agree on which were the principal diseases and which were complications or accessory. In 32 cases there was a relative agreement, all being credited with the same diseases, but not necessarily in the same order of importance. By adding these 32 to the 18 already mentioned, it could be claimed that approximate agreement had been achieved in only 42% of the total. A substantial degree of disagreement was noted in particular with regard to atherosclerotic, rheumatic, hypertensive, and other forms of heart disease. Commenting on these findings, Ustvedt confessed that, far from solving any problem, they raise a whole series of questions, calling for uniformity of diagnostic criteria, uniformity of nomenclature, and some coordination within hospitals over material for statistical handling.

Rheumatic Fever.—Höst and Ustvedt (*Tidsskrift for den norske lægerforening*, Sept. 15, 1958) used a modification of the Duckett Jones system of criteria for the diagnosis of rheumatic fever in an attempt to ascertain what changes this disease may have undergone in the recent past. The 174 cases observed at Ullevaal Hospital in the three-year period 1931-1933 were compared with the 121 cases in the five-year period 1952-1956. The hospital records of each of these 295 cases was critically scrutinized with regard to the diagnostic criteria used. There was complete agreement with the Jones criteria in 86% of the first and 81% of the second group. In both groups it would thus seem that the diagnoses had, on the whole, reflected discriminating accuracy. To judge by this comparison the disease has shifted in character, with fewer severe cases with involvement of the heart and fewer relapses. While in the first group the sexes were equally represented, females predominated in the second group in the ratio of 3:2. Patients under 20 years of age were equally represented in the two groups, but whereas only 7% of the patients in the first group were over 50, this was the case with 27% in the second group. In a retrospect of earlier publications on the subject, it is pointed out that opinions as to the decline in the frequency and severity of rheumatic fever have been unavoidably vague for want of straightforward criteria which render a disease like pernicious anemia amenable to accurate diagnosis. At present, the closest approach to accuracy is by such a system of criteria as that used by Duckett Jones.

The State Institute of Public Health.—With its staff of 14 physicians, 8 pharmacists, and a budget running into many millions, the State Institute of Public Health in Oslo is now so much taken for granted that there is risk of the services it renders to the community being overlooked—hence the importance of its annual report for 1957 (supplement to *Tidsskrift for den norske lægeforening,* Aug. 15, 1958). Most of the bacterial vaccines, toxoids, and serums needed in Norway are produced by the institute's serum department. Those vaccines that have to be imported from abroad include that for poliomyelitis which is imported from Denmark and the United States and small quantities of certain typhus, plague, and yellow fever vaccines. The cowpox vaccine department is the sole producer of cowpox vaccine in Norway. Attempts are being made to reduce the bacterial content of the calf vaccine and to increase the stability of cowpox vaccine grown on tissue cultures. In 1957 a case of postvaccinal encephalitis with recovery was reported. There is also the bacteriological department which carries out bacteriologic and serologic tests. In 1957 there were 47,787 specimens examined for tubercle bacilli. The serodiagnosis department includes a Wassermann laboratory which in 1957 examined 83,741 specimens for the diagnosis of syphilis by complement fixation and flocculation tests. Another laboratory dealt with influenza problems, including those raised by the epidemic in the last four months of 1957. Another unit is the chemistry department which is concerned with chemical investigations of drinking water and sewage. In 1957 the methodology department was created. It deals with special problems in the fields of microbiology and biochemistry.

Shortage of Radiologists.—At the end of last year about 50% of the hospital posts for radiologists were vacant for want of applicants. This illustrates the working of the law of demand and supply, but it must be carefully explained to the public hospital authorities who have not hitherto fully appreciated what it costs to become a radiologist. As pointed out by Dr. O. Grönvik, chairman of the Junior Physicians Association, the physician who has graduated as such must take six to seven additional years in order to qualify as a fully trained radiologist, having under the best of circumstances to spend four of these years in the radiological department of a hospital. The health authorities have decided that the radiologist must not exceed a 40-hour week on account of the dangers inherent to his work, but in practice no Norwegian radiologist keeps within this limit, such is the call on his services. Even when a young radiologist becomes qualified for one of the relatively few high appointments, he may hesitate before accepting it for fear of finding himself swamped by work for which he has no assistant. Something could be done to encourage the recruiting of junior radiologists by allowing them certain emoluments hitherto denied them in certain hospitals. Although the practice of such hospitals to pay the surgeon called on to deal with a casualty brought to hospital but to pocket the corresponding fee charged the patient for the services of radiologist working in cooperation with the surgeon has led to disputes, it is not so much a matter of fees in isolated instances as the long-term future of the would-be radiologist that is making him hesitate in his choice of calling. Because it takes so long to become a radiologist, there is little prospect of the present stalemate being corrected in the near future.

SWITZERLAND

Iproniazid and Angina Pectoris.—Schweizer and von Panta (*Schweiz. med. Wchnschr.* 88:822, 1958) gave 150 mg. a day of iproniazid to 100 ambulatory patients with angina pectoris for 12 to 222 days. The pain on effort disappeared in 48 patients and was improved in 49. In three the drug had no effect; 63 were completely and 29 partially relieved from pain at rest. Improvement was noted after an average of 7 (2 to 18) days. The optimal therapeutic effect was reached before the 20th day and remained constant during the trial period in 98 patients. After the drug had been discontinued, pain reappeared in 74 within 10 to 20 days. The electrocardiogram at rest remained unchanged in 57 patients; the ischemic changes decreased in 30 and increased in 13. The arterial pressure was diminished in 25% of the normotensive and in 73% of the hypertensive patients. In 40% there was an orthostatic hypotension. A decrease of the hypotensive effect of iproniazid during the trial period was observed in 36 patients. Serious complications occurred in 14 patients: myocardial infarction in 4, cerebrovascular accident in 2, congestive heart failure in 4, urinary retention in 2, and psychosis in 2. Three patients died, two with myocardial infarction and one with cerebrovascular accident.

Such undesirable side-effects as impotence, insomnia, and constipation were observed in 89 patients. These side-effects made it necessary to cease the trial in 46. In most of these patients the drug had a marked effect on the pain. Unfortunately the side-effects prohibited the administration of an effective dosage over a prolonged period of time in about half the patients. In most, the effective dosage was 150 mg. a day. It cannot yet be stated whether or not a drug tolerance develops. There are no indications that iproniazid has any effect on the myocardial ischemia or on the natural course of the disease. On the other hand the disappearance of the signal pain has not been proved to be harmful. The danger of serious complications necessitates careful observation of the patient. In the presence of cerebral arteriosclerosis or of a marked increase of the size of the heart, the administration of iproniazid is not advisable.

UNITED KINGDOM

Public's Views on Cancer.—The public's views on the cause of cancer were obtained through interviews with a random sample of the adult population of Edinburgh by Cartwright and Martin (*Brit. M. J.* 2:592, 1958). Only 1% of those questioned knew that cancer could attack children. Between 25 and 33% considered it primarily a disease of persons above the age of 45. There were no indications of cancerophobia in the population at large. When asked which of five selected causes of death was responsible for the greater number of deaths in the population, 35% said heart disease, 32% said traffic accidents, and 27% said cancer. Women were more cancer-conscious than men. Of those questioned, 75% thought that cancer was ultimately fatal, and more than 33% said that they would rather not know if they had cancer. It is now quite widely believed that smoking is a cause of cancer. When asked specifically, 30% said that smoking was a possible cause. The cause of cancer most frequently suggested was knocks, bumps, or bruises. Then in descending order of frequency came smoking, air pollution, inheritance, fatigue, worry, and "overstrain." No opinion on the cause of cancer was given by 34%, and 12% thought that it was communicable. Curiously enough, the number of people who gave up smoking on the grounds of expense was greater than those who gave it up for health reasons.

Psychological Medicine in General Practice.—A working party of the Council of the College of General Practitioners studied psychological medicine in general practice at the request of the Ministry of Health (*Brit. M. J.* 2:585, 1958). They found that psychological medicine was an integral part of all general practice. Every good family physician must be a good psychologist. To misdiagnose psychological illness is just as bad as misdiagnosing organic disease and may lead to even greater unhappiness. So much medical teaching is concerned with organs and tissues that the family doctor may lose sight of the patient as an individual with fears, anxieties, guilt feelings, and inadequate relationships with other people. It is considered by general practitioners that about 30% of their patients have some form of psychiatric disturbance. These fall into five main groups which frequently overlap. They are anxiety and depression from emotional stress, constitutional liability to anxiety or depression, constitional personality and behavior difficulties, psychoses, and organic brain disease. The last two are comparatively rare, but involutional depression and arteriosclerotic senile dementia are by no means uncommon.

Every organic illness has its natural psychological component, which may be hardly noticed or severe. Such conditions as cancer, venereal disease, arthritis, and heart disease may be accompanied by superadded emotional upset, while others—premenstrual tension, spastic colon, ulcerative colitis, asthma, and eczema—are on the borderline between the physical and psychological. Certain symptoms are particularly prone to cause reactive anxiety or depression. Many of these patients with psychological disturbances have to be supported and managed by their family physician. The general practitioner starts with an advantage over the consultant in the management of these patients because of his knowledge of their background and their families. Responsibility for mental health will rest more and more on the general practitioner in the future. A great deal remains to be done before he is skilled enough and adequately equipped to do as good work in this field as he is able.

Psychological medicine should be taught more thoroughly to all medical students, and more opportunities for postgraduate training in it should be open to all general practitioners. It might be advantageous for a group of physicians to have one partner who, though still in general practice, has been specially trained in this branch of medicine. In helping their patients with psychological illnesses family doctors should take more opportunity to develop team-work in the ancillary health services to which they have access. The Ministry of Health should investigate the possibility of giving more opportunities and recognition to general practitioners with a special interest in psychological medicine.

Ischemic Heart Disease.—Thomas and co-workers estimated the prevalence of ischemic heart disease in South Wales (*Lancet* 2:540, 1958). The cardiovascular status of 100 miners from an industrial area was compared with that of 100 men from an agricultural area nearby. The age range was 55 to 64. A pilot survey in which clinical, radiologic, and electrocardiographic evidence was used for diagnosis suggested strongly that the electrocardiogram was the most useful in assessing cardiac status. The clinical examination was sometimes of value, but the posteroanterior chest x-ray was of little diagnostic aid. The same clinician made a diagnosis on the clinical and electrocardiographic evidence, and all electrocardiograms were interpreted by three cardiologists, whose findings varied widely. Two indexes of ischemic heart disease were used—the clinical index, based on clinical assessment, electrocardiography and radiography by one cardiologist, and the electrocardiographic index, based on agreement between three cardiologists that an electrocardiogram showed changes compatible with the diagnosis of ischemic heart disease. The prevalence in these men, based on clinical assessment, was 25% in the agricultural area and 38.3% in the mining area. The figures based on electrocardiographic assessment were 17% and 21.3% respectively. Though the mining group seemed to have a somewhat higher prevalence of ischemic heart disease, the difference was not statistically significant. Those affected were both taller and heavier than the others. The siblings of the men with ischemic heart disease had a higher mortality than the siblings of the controls. No significant difference was noted in the mean serum cholesterol levels in those with and those without ischemic heart disease.

New Hypoglycemic Agent.—The results obtained in 43 diabetics treated with a new hypoglycemic agent, chlorpropamide, were reported by Murray and co-workers (*Lancet* 2:553, 1958). Chlorpropamide, or N(propyl-N-chlorobenzene) sulfonyl urea, which is chemically related to carbutamide and tolbutamide, was given to a group of diabetics who had had diabetes for less than 10 years, who were either not taking insulin or had not been taking it for more than two years and who were over 40 years old. Diet alone failed to control the diabetes in most of these patients. Thirteen were hospitalized, and 30 were outpatients. The drug was given as a single daily dose of 1 Gm. orally. If after a few days treatment a good response was obtained, the dose was reduced to the lowest effective level. A satisfactory hypoglycemic response was obtained in 28 of the 43 patients treated, or in 65%. Ketonuria had been previously noted in 27% of the failures, compared with 4% of the successes. If a favorable response occurred, judged by a sugar-free urine, it did so by the second or third day, and always within a week. In the responders the mean blood sugar level fell from 273.5 mg. per 100 ml. before treatment to 161.8 mg. at the end of two weeks, while in the nonresponders the mean figures were 364.5 mg. and 304.5 mg. The mean daily glucose output was reduced from 35.5 to 3.4 Gm. in the responders, and in the nonresponders it remained constant at 58 to 60 Gm. daily.

Over half the responders had been previously treated with carbutamide or tolbutamide. The impression gained was that chlorpropamide was less potent than carbutamide but more potent than tolbutamide. Increasing the dosage to 3 Gm. daily brought under control three patients who did not respond well to 1 Gm. daily initially. As it was not thought desirable to give more than 1 Gm. daily, this dosage was considered excessive and the cases were regarded as failures. There were no serious toxic effects, such as leukopenia or thrombocytopenia. Nine patients complained of nausea, a diffuse erythematous rash, and drowsiness. Increasing the daily dose from 1 to 2 Gm. often caused these side-effects.

Cost of Iron Preparations.—The cost of iron preparations for oral use in general family and hospital practice was investigated by Davidson and Richmond (*Lancet* 2:570, 1958). They stated that ferrous sulfate tablets, with or without added trace elements, and whether bought as a proprietary or nonproprietary preparation, were the cheapest form of iron for oral medication. Since ferrous sulfate raises the hemoglobin level as effectively as other iron salts, such as the gluconate and succinate, and, when given in comparable doses of elemental iron, is no more likely to cause gastric upsets, it should be the first choice for oral iron therapy. An analysis of hospital prescriptions showed that ferrous sulfate forms 46% of all the iron preparations prescribed, while the newer organic iron preparations form 54%. In general practice, however, ferrous sulfate tablets form only 23% of all the iron preparations prescribed, whereas the more expensive organic preparations form 77%. The cost of iron tablets to the National Health Service is about $150,000 per month, but if ferrous sulfate were always prescribed whenever iron for oral use is required, the annual saving would be nearly $1,000,000.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Effect of Acute Digitalization in Patients with Rheumatic Heart Disease. L. Werkö, H. Eliasch, B. Thomasson and E. Varnauskas. Cardiologia 33: 161-194 (No. 3) 1958 (In English) [Basel, Switzerland].

The immediate effect of the administration of cardiac glycosides was studied in 56 patients with rheumatic heart disease. Four of these patients had aortic valvular disease only, 31 had pure mitral stenosis, 1 had mitral incompetence, 8 had multivalvular involvement, and the remaining 12 had mitral stenosis associated with other disease. Ten patients were in congestive failure. In 20 patients the clinical diagnosis was confirmed by autopsy. Lanatoside C was given to 37 patients in a dose varying between 0.4 and 1.6 mg., strophanthin K was given to 11 patients in a dose of 0.5 mg., Scillaren was given to 6 patients in a dose varying between 0.5 and 1 mg., and acetyldigitoxin was given to 3 patients in a dose of 0.6 mg. The cardiac output and the pressures in the pulmonary and systemic circulations were determined before the drug was administered and 30 and 60 minutes after the drug was given. In 6 patients the response to 10 minutes of exercise was studied 30 to 40 minutes after the drug was given. In 2 patients similar exercise studies were performed both before and 30 minutes after lanatoside C had been administered. In 7 patients the effect of the cardiac glycoside was studied after the extracellular fluid volume or plasma had been increased by rapid intravenous infusions of crystalloid or colloid solutions. In 2 patients pulmonary edema occurred early in the procedure. In these patients the effect of therapy with lanatoside C and strophanthin K, respectively, was studied before any other treatment was instituted.

It was found that in acute digitalization the right atrial pressure decreased in all patients. This decrease was of physiological significance only in the patients with right heart failure (from 10.8 ± 1.54 to 4.8 ± 0.95 mm. Hg). The pulmonary arterial blood pressure decreased in some patients, and its drop was most pronounced in the patients with atrial fibrillation who were not in congestive heart failure (39.8 ± 4.09 to 31.2 ± 3.34 mm. Hg). The cardiac output increased only in the patients in congestive heart failure. The stroke volume increased only in the patients with atrial fibrillation: in those not in congestive failure, from 39.8 ± 4.45 to 51.1 ± 5.09 mm. Hg; in those in congestive failure, from 36.7 ± 4.61 to 48.2 ± 5.73 mm. Hg. The heart rate usually decreased. This was most marked in patients with atrial fibrillation. Strophanthin K and Scillaren had the most rapid action, but the rapidity of action of lanatoside C and acetyldigitoxin almost equalled that of the first 2 drugs. Otherwise no difference was found among the drugs. The exercise tolerance was greatly improved in the patients with atrial fibrillation but not in those with sinus rhythm. Digitalization did not influence the hemodynamics to any great extent in the patients without congestive failure in whom the plasma volume was increased with infusions of crystalloid or colloid solutions. In 2 patients severe pulmonary edema occurred in the course of treatment. The edema did not disappear as a result of treatment with lanatoside C in one patient and with strophanthin in the other; administration of oxygen relieved the anoxia, and after additional administration of morphine and theophylline the edema disappeared.

Patients with mitral stenosis and sinus rhythm should be digitalized only if they have signs of congestive heart failure or if left ventricular failure is suspected (in the presence of arterial hypertension, mitral incompetence, or aortic valvular disease). Patients with mitral stenosis and atrial fibrillation should always be digitalized regardless of the occurrence of signs of failure of the right heart. Further studies regarding the behavior of patients with mitral stenosis during exercise in different stages of digitalization seem to be indicated.

Some Aetiological Aspects of Coronary Heart Disease: An Indian Point of View Based on a Study of 867 Cases Seen During 1948-55. R. P. Malhotra and N. S. Pathania. Brit. M. J. 2:528-531 (Aug. 30) 1958 [London].

The authors report on 754 men and 113 women with coronary heart disease who were admitted to hospital or seen in private practice in Amritsar in the Punjab, India, between 1948 and 1955. Obser-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1949 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

vations on these patients concerning age (including the younger age groups), profession, family history, body build in general, and association with diabetes mellitus and hypertension did not in any way differ from those of Western workers. The ratio of men to women was more or less the same as that described by Western workers; thus, the degree of relative immunity from coronary disease enjoyed by the female sex in India is no greater than in the West despite the fact that women lead a comparatively much more sheltered and indoor type of life, that they are mostly vegetarians, and that addiction to tobacco or alcohol is practically unknown among them.

The role of the fat content of diet in the causation of coronary disease is a controversial point. The fat content of the diet taken by most of the 867 patients was poor as compared with European standards. Consequently it seems difficult to believe that dietary fat can play any significant part in the causation of coronary disease. The observations on these patients showed that vegetarians are no less prone to the occurrence of coronary disease, and the same is true of nonsmokers, since no less than 50% of the patients belonged to the Sikh sect whose religion forbids smoking. Obesity has long been recognized as an important predisposing factor. Of the 754 men, 204 were obese, 500 were of average type of build, and 50 were thin; of the 113 women, 48 were obese, 57 were of average type of build, and 8 were thin. These data suggest the greater importance of obesity in the causation of coronary disease in women than in men.

Coronary disease is a major cause of deaths in countries that are materially more advanced. Of the 867 patients, only 123 (14%) were from rural areas, but this finding does not justify the assumption that the disease is less prevalent among persons living in places remote from modern civilization. Patients from villages came to the town hospitals only when they were severely disabled by congestive heart failure or when their physical activity was seriously curtailed by severe anginal pain on effort. Brief or mild episodes of coronary disease remained unnoticed, and the same was true for sudden deaths. Furthermore, small villages near big towns cannot be considered rural in the real sense of the word. A great deal of work and money would be required for an investigation in those remote areas of India in which the mode of life continues to be what it was in the 18th century. With the present standard of vital statistics in India, it is difficult to give the true incidence of coronary disease in this part of the world. But with 867 cases of coronary disease (28.4%) occurring among a total of 3,054 patients with diseases of the heart seen during the observation period, it is difficult to share the view held by Western workers that coronary disease is uncommon in materially less-favored countries.

Traumatism in the Pathogenesis of Primary Rheumatism. L. Schiavetti and A. Gospodinoff. Policlinico (sez. prat.) 65:1015-1025 (June 30) 1958 (In Italian) [Rome].

The authors reviewed the history of 400 patients with rheumatic disease, who were treated at the Center of Rheumatology in Rome during the period 1952-1957, and found that 14 of them (3.5%) had a post-traumatic rheumatic arthritis. Traumatism is probably an aspecific, pathogenetic factor which contributes to the clinical manifestation of primary rheumatism (rheumatic fever, rheumatoid disease, and ankylosing spondylitis) in persons who are predisposed to the disease. This correlation was more clearly observed in instances of acute rather than in chronic rheumatic disease. A period varying between 13 and 25 days elapsed between the traumatic episode and the manifestation of the rheumatic disease.

The case of a woman, aged 36 years, is reported, which illustrates the pathogenetic correlation between traumatism and primary rheumatic disease. The patient had had post-traumatic hydrarthrosis in the right knee 4 years previously. The synovial fluid showed no evidence of inflammatory reaction, and the disorder subsided shortly. However, swelling associated with an intra-articular inflammatory exudate reappeared 3 months later, and after that at irregular intervals. The disease developed into intermittent hydrarthrosis. An injury to the left hand, which occurred 2 years later, was followed by rheumatic arthritis; this process involved the patient's ankles and knees the following year.

The correlation between traumatism and primary rheumatic disease is also relevant in problems of health insurance and industrial health. The physician sometimes has to evaluate the extent to which a mechanical injury has contributed to the development of a rheumatic disease, or he may be called upon to dissuade persons who are predisposed to rheumatic disease from engaging in activities exposing them to acute or chronic mechanical injuries.

Dicumarol and Serum Uric Acid. O. E. Hansen and C. Holten. Ugesk. læger 120:974-975 (July 24) 1958 (In Danish) [Copenhagen].

A uricosuric effect of Dicumarol has been observed. In most of the 40 patients given anticoagulant treatment with heparin prolongatum and Dicumarol, there was a reduction of over 20% in the serum uric acid value. The uric acid determinations were made as double measurements according to the Praetorius method. The question is raised as to what extent the improved prognosis in ischemic cardiac disorders after treatment with anticoagulants depends only on the prolonged coagulation time, or whether the effect of these agents on the uric acid metabolism may be significant.

The Salicylate Problem with Special Reference to Methyl Salicylate. H. M. Cann and H. L. Verhulst. J. Pediat. 53:271-276 (Sept.) 1958 [St. Louis].

The widespread use of acetylsalicylic acid, the extreme toxicity of methyl salicylate, and the public's unawareness of the toxicity of these substances are the main reasons for the extent of this problem. When a child has accidentally ingested a salicylate product, treatment should be started as soon as possible. In all cases the stomach must be emptied promptly, and mild intoxication can be remedied by this procedure alone. Since methyl salicylate delays stomach emptying, gastric lavage may, therefore, be carried out as long as 4 to 6 hours after ingestion. If gastric lavage is performed, sodium bicarbonate should not be used, since it enhances salicylate absorption from the gastrointestinal tract. In 2 of the 3 cases cited, in which children died from accidental ingestion of methyl salicylate (wintergreen oil), despite labeling on the bottle, the warning was not heeded that the drug should be "kept out of the reach of children." In none of the 3 cases were immediate attempts made to empty the stomach, and proper therapy was delayed. In one case the similarity of a methyl salicylate container and a cough medicine container was apparently the cause of the fatal accident. The practice of some physicians in advising hospitalization—if only for overnight observation—in most cases of salicylate ingestion, whether or not symptoms have occurred, emphasizes the necessity of prompt, vigorous therapy and close observation in all instances of salicylate overdosage. The latter is especially important in methyl salicylate poisoning where the usual asymptomatic period after ingestion makes prolonged observation mandatory.

In acute salicylate poisoning, water is lost from the body by diaphoresis, hyperpnea, vomiting, and diarrhea, which loss results in impaired renal function and decreased salicylate excretion. The hypoprothrombinemic effect of salicylates, which can be corrected by the administration of vitamin K preparations, is well known. The treatment of established salicylate intoxication consists of giving fluids intravenously (orally in mild cases) to correct the existing water deficit; dextrose is administered to combat ketosis, intravenously administered calcium gluconate is given in the event of tetany, and oxygen should be administered if convulsions occur. Base solutions are contraindicated in the early stages, as they may lead to tetany, convulsions, and death, and they should not be given until acidosis supervenes some 4 to 6 hours later. Although there are some individuals who feel that sodium bicarbonate is not harmful when given early in the course of the development of symptoms, and despite the fact that renal excretion of salicylates is enhanced in the presence of an alkaline urine, base therapy must be administered cautiously, as rapid correction of the acidosis may result in alkalosis. Barbiturates, paraldehyde, and morphine are definitely contraindicated because of their synergistic effect with the salicylates in producing central nervous system depression. Good clinical results have been obtained with hemodialysis, and exchange transfusion has been used in cases of methyl salicylate poisoning with favorable results.

The 1957 Influenza Epidemic: A Study of 500 Cases Admitted into the J. A. Group of Hospitals, Gwalior, M. P. P. N. Laha and D. R. Bapat. J. Indian M. A. 31:53-58 (July 16) 1958 (In English) [Calcutta].

The authors report on 477 adults and 23 children with influenza who were admitted to a group of hospitals in Gwalior, Madhya Province, India, between June 1 and July 31, 1957, when the influenza epidemic engulfed the Gwalior area which includes 3 towns, namely, Lashkar, Gwalior, and Morar. The cases of influenza were distributed among the 3 religious groups (Hindu, Moslem, and Christian) in proportion to the number of persons in each group. Most of those affected (74.2%) were between the ages of 16 and 30 years. Males predominated in a ratio of 7 to 1 among adults and of 5 to 1 among children. The epidemic affected persons of every variety of occupation. Roughly estimated, the attack rate at Gwalior was 20% of the population. Fever, headache, cough, and body ache constituted the major tetrad of symptoms. Weakness and lassitude were present in only 4.2% and giddiness in only 2.1% of the patients. There was a small proportion of patients with only local symptoms, such as coryza and sore throat. Vomiting and rigor were sometimes very prominent in children, and atypical symptoms, such as dyspnea, giddiness, and increased frequency of micturition, were also observed. Laboratory studies were done on 100 patients; 91 of these had a normal white blood cell count, 5 had leukocytosis, and 4 had leukopenia. The erythrocyte sedimentation rate was increased in 84 patients and was normal in 16. The course of the disease lasted from 3 to 5 days in most of the patients, but in some patients it was prolonged to 7 days. There were no significant complications. The relapse rate was about 5%. There were no deaths.

All the patients were treated in separate wards to prevent spread of the infection to other patients in the hospital. The patients were kept under complete rest for at least 4 days even after the temperature was restored to normal, since premature activity was an important cause of relapse. Of the 500 patients, 237 were given salicylates, and 193 received salicylates and intramuscular injections of crystalline penicillin; 30 patients were treated with salicylates, crystalline and procaine penicillin, and dihydrostreptomycin, 20 with sulfonamides, and 20 with crystalline penicillin alone. The number of days required to cure the patients ranged from 3 to 7 in each of the 5 groups. It was concluded that drugs did not modify the course of the disease.

Blood Ammonia Determinations in Liver Diseases. Li P'ei-Kuang, Lu Han-Ming, Ho Chih-Hsiung and others. Chinese M. J. 76:529-542 (June) 1958 (In English) [Peking, China].

The relationship of the liver and of the portal circulation to the metabolism of ammonia was recognized more than 60 years ago when the syndrome called "meat intoxication" was observed in Eck-fistula dogs with high blood ammonia levels. Later evidence was found that the elevation of blood ammonia levels might be one of the important causes underlying hepatic coma. The occurrence of episodic stupor in patients who have undergone portacaval anastomosis is likewise associated with elevated blood ammonia levels. The authors made 226 determinations of the ammonia content of the peripheral blood in 97 patients with a variety of liver diseases and several miscellaneous conditions, with or without involvement of the liver. The blood ammonia was determined by Conway's microdiffusion technique, as modified by Ting and Liu. Results were expressed in micrograms of ammonia-nitrogen per 100 ml. of blood. In normal controls the figures ranged between 20 and 50 mcg. per 100 ml., and 50 mcg. per 100 ml. was therefore accepted as the upper normal limit.

The authors have tabulated the ammonia-nitrogen values obtained in patients with cirrhosis of the liver, hepatitis mostly of viral origin, primary carcinoma of the liver, amebic abscess of the liver, schistosomiasis, nephritis, gastrointestinal diseases, cardiac disorders, and miscellaneous diseases. The results suggest that the ammonia-nitrogen values may, to a certain extent, reflect the functional state of the liver. An elevation of the ammonia level is usually observed in cases of liver diseases with diffuse parenchymatous damage and portal-systemic shunt or collateral circulations. In hepatic coma or precoma the ammonia-nitrogen values are usually very much elevated, greatly exceeding the values observed in the same patient during the absence of coma. It is, therefore, believed that the disturbance of ammonia metabolism must be one of the important causes of hepatic coma.

The ammonium chloride tolerance test was made in a group of patients with and in a group without hepatic insufficiency and collateral circulation. The results of this test differed greatly in these 2 groups, and it is suggested that this test may supplement the simple blood ammonia-nitrogen determinations.

Primary Renal Hypokalemia–Primary Aldosteronism. G. Alsted and P. Halberg. Ugesk. læger 120:979-982 (July 24) 1958 (In Danish) [Copenhagen].

The differential diagnosis between primary renal hypokalemia and primary aldosteronism is difficult but extremely important. In hypokalemia continued potassium treatment must be applied, while aldosteronism can be cured radically by operation. A case of potassium-losing nephritis in a woman, aged 43 years, is described. There had been no previous renal disorder. The chief symptoms were loss of weight, progressive muscular adynamia, slight proteinuria, polydipsia, polyuria, and hyposthenuria. There were hypokalemia and typical changes in the electrocardiogram. Potassium therapy was instituted, but the patient died within 2 weeks after admission. At autopsy nephrotic changes were found in the kidneys, but there was no evidence of acute or chronic renal infection. The adrenal glands were morphologically normal; the pituitary gland was somewhat enlarged; and microscopic examination revealed an increased number of basophil cells in small adenoma-like groups. Technical facilities for determining the aldosterone excretion were not available. Because of the findings in the hypophysis and the absence of primary infectious renal changes, and in spite of the absence of a tumor in the adrenal cortex, the case is regarded as one of primary aldosteronism.

UROLOGY

Retrograde Ejaculation as Cause of Sterility in the Male. A. M. C. M. Schellen. Nederl. tijdschr. geneesk. 102:1252-1253 (June 28) 1958 (In Dutch) [Amsterdam].

The author presents the history of a 35-year-old man who had been married for 8 years but who had no children. The history revealed that during coitus the patient had the sensation that, while semen was expelled, there was no ejaculum. Since the patient's genitalia seemed to be free from pathological changes, he was told to urinate shortly before and shortly after cohabitation and to collect the postcoital specimen for examination. Two postcoital specimens of urine revealed the presence of normal spermatozoa. The author feels that the patient has an idiopathic form of retrograde ejaculation. If a patient with this condition requests treatment for sterility, urologic therapy may be contemplated but is often found impracticable. Artificial insemination may be effected with seminal fluid obtained from the patient's bladder. The author found reports of 8 similar cases in the literature and believes that more cases will be recognized if retrograde ejaculation is thought of in patients with aspermia.

Vesicoureteral Reflux in Children. B. W. Jones and J. W. Headstream. J. Urol. 80:114-115 (Aug.) 1958 [Baltimore].

The authors report on 70 boys and 30 girls, their ages ranging from 14 days to 14 years, who were subjected to voiding cystography in order to determine whether reflux occurred in children without history or findings suggestive of urinary tract disease. These patients had a nonurologic admission with a negative urinalysis. Of the 100 children examined by voiding cystography, only 1 exhibited vesicoureteral reflux. Subsequent examination of the patient with vesicoureteral reflux revealed bladder neck contracture, and a transurethral resection was performed with an uneventful postoperative course. Follow-up studies 6 months later demonstrated bilateral reflux on voiding cystography, no residual urine, and negative urinalysis. It is the authors' belief that children with normal urinary tracts will not exhibit vesicoureteral reflux. Thus, this study supports the findings of those who claim that vesicoureteral reflux occurs only in the presence of demonstrable uropathy.

OTOLARYNGOLOGY

Executive's Dysphonia: A Study of 49 Patients. W. H. Gardner. Cleveland Clin. Quart. 25:177-186 (July) 1958 [Cleveland].

The subjects of this study were 49 business men who had been referred for examination of the voice. The majority were from sales and personnel departments. They were selected on the basis of 2 criteria: (1) the patient held an executive position that involved command of and communication with a large number of persons, and (2) his vocal disorder could be classed as functional dysphonia. The patients ranged in age from 32 to 70 years. Forty-four of the 54 findings among the otolaryngologists were in patients with functional dysphonia, 6 in those with contact ulcers, and 4 in those with nodules. Chronic rhinitis was the single most frequent finding. The duration of the vocal disorders ranged from 1 month to 20 years. The 49 patients reported 243 symptoms: 153 by those having functional dysphonia, 63 by those having contact ulcers, and 27 by those having nodules. Hoarseness was reported by all the patients. A total of 194 vocal deviations, including hoarseness, monotony, and breathy voice, were observed by the voice therapist, an average of 4 deviations per patient. More than half of the 49 patients had limited ranges of speaking pitch.

In addition to voice therapy that was recommended for all 49 patients, antihistaminics or hypoallergics (16), diet and vitamins (16), no smoking (6), prednisone (3), and tranquilizers (2) were advised for 43 of the executives having dysphonia. Voice therapy was successful in all of the 37 patients who participated in the program; 31 achieved clear voices, and 6 had improved voices. In 9 of the 10 patients having contact ulcers who received voice therapy, the ulcers disappeared or improved; and in 5 of the patients having nodules, the nodules cleared or improved. The remaining 3 patients having contact ulcers who refused therapy remained unimproved; 1 of these developed an additional granulation requiring surgery. Of the 9 patients having functional dysphonia who did not receive voice therapy, 5 refused the therapy and appeared to be satisfied with the results of tranquilizers; 3 refused the therapy because they were "too busy"; and 1 was referred to another therapist. The author is of the opinion that the best results are obtained with a combination of voice therapy and medical measures.

Intermittent Parotid Swelling Due to Ill-Fitting Dentures—An Entity; Its Diagnosis and Treatment. A. C. Furstenberg and I. M. Blatt. Laryngoscope 68:1165-1181 (July) 1958 [St. Louis].

The authors report on 3 women, between the ages of 46 and 72 years, with diffuse parotid swelling associated with pain and a feeling of pressure in the cheek while eating. All 3 patients had been wearing complete or partial dentures for many years. When salivary flow was stimulated by lemon, the parotid gland swelled. On massage of the parotid region, only a sluggish flow of clear saliva from a hypertrophic parotid papilla was noted. The cordlike dilated Stensen's duct was palpable along its buccomasseteric course. On probing the duct, dilated segments alternated with strictures. The wall of the duct imparted a gritty sensation on probing; this was caused by the hypertrophic and metaplastic duct epithelium.

This condition of parotid swelling appears definitely to be associated with the presence of dentures. The patient is required to alter the mechanism of mastication in a manner which does not sustain the normal chewing habit. As food is being chewed on one side of the mouth, the parotid papilla on the opposite side tends to be sucked mesially and bitten. Mastication is further rearranged and altered when alveolar absorption occurs, allowing the dentures to shift about while chewing. When the parotid papilla is subjected to repeated trauma and inflammation, fibrous tissue proliferation and scar tissue cicatrization occur. This interferes with normal salivary flow, and the ensuing pressure behind the stricture results in dilatation of the duct of the gland. Secondary bacterial infection supervenes with a diffuse inflammatory reaction along the buccomasseteric course of Stensen's duct and with production of multiple inflammatory strictures. If a stricture in the secondary or tertiary ducts seals off a section of secreting acinar tissue, an inflammatory cyst may be formed. Secretory sialography is useful in making the diagnosis and in differentiating the condition from nonobstructive sialectasis.

Surgical treatment in this series consisted of subtotal parotidectomy on one patient, in whom an inflammatory cyst was revealed by the parotid sialogram. Dochoplasty was carried out on the other 2 patients. Healing was prompt. Rapid regression of parotid swelling occurred in all 3 patients, and they remained asymptomatic. Microscopic examination of the surgical specimen revealed stenosis, scar tissue formation, and metaplasia of the duct epithelium. All these findings were compatible with traumatization of the parotid papilla. The syndrome of obstructive sialodochitis, with intermittent parotid swelling caused by ill-fitting dentures, may be regarded as a definite entity.

THERAPEUTICS

Advantages and Limitations of Additional Treatment of *Tuberculous Meningitis* with Corticosteroids. B. Dieckmann. Beitr. Klin. Tuberk. 118: 252-261 (No. 4) 1958 (In German) [Berlin].

The author reports on 8 women and 6 men with tuberculous meningitis, who were treated continuously with streptomycin and isoniazid until their cerebrospinal fluid was restored to normal; 1 Gm. of dihydrostreptomycin was given first daily and later twice weekly by intramuscular route, and 10 to 20 mg. of isoniazid was given orally. Seven of the 14 patients received, in addition, cortisone, hydrocortisone, or prednisolone orally, and 2 patients with spinal block received these drugs also by lumbar and cisternal route. The survival rate in both groups of patients was the same; a 50-year-old man in the cortisone group died after temporary improvement at the end of the 11th week of treatment, and a 54-year-old woman in the other group died in the 4th week. The surviving patients in the cortisone group were followed for 1 to 1½ years and those in the other group for 2 to 4 years after their discharge from the hospital. All 12 surviving patients remained free of recurrences, but one of those who had not received cortisone therapy still had spastic paresis of both legs and another had paralysis of the right peroneus muscle. Two women in the cortisone group also had residual neurological symptoms. The body temperature of the patients in the cortisone group was restored to normal in one-third the time required by those in the other group. Drop of temperature by crisis did not occur in any of the patients; defervescence occurred within 2 to 6 weeks.

The cerebrospinal fluid of the patients in the cortisone group was restored to normal (with cell values not exceeding 30 per cubic millimeter, glucose content at least 50% of the actual blood sugar level, and protein level below 25 mg. per 100 cc.) in two-thirds the time required by those in the other group, i. e., 15 weeks, on the average, in the cortisone group as compared with 22 weeks in the other group. Exacerbations no longer occurred after that time. The more rapid normalization of the spinal fluid was reflected not only by the reduced number of cells but also by the glucose level. The protein level dropped rapidly except in one patient with spinal block; in the latter, however, block systems were no longer demonstrable at the end of 21 weeks of therapy after he had received 15 to 30 mg. of prednisolone orally daily and 12.5 mg. of hydrocortisone every second or third day by the cisternal route for 10 weeks. Improvement of the general condition was impressive in the cortisone group; within a few days of therapy there was a fundamental change, with clearing of consciousness, euphoria, increased appetite, and increase in body weight. There were no significant untoward reactions. Slight hypopotassemia was compensated by oral administration of potassium chloride. The shortened duration of treatment also had the advantage that less streptomycin and isoniazid had to be given.

Rapid improvement of the general condition, rapid defervescence, and marked shortening of the duration of treatment are the advantages of the combined antituberculous and cortisone therapy. The expectations concerning the removal of the obstruction in the spinal canal and that of neurological complications were not fully justified.

Treatment of Biermer's Disease with a Combined Preparation of Intrinsic Factor and Vitamin B_{12}: Clinical Trials. P. Croizat, L. Revol, R. Creyssel and others. Presse méd. 66:1204-1206 (July 2) 1958 (In French) [Paris].

A French proprietary preparation, containing 125 mg. of intrinsic factor, 100 mcg. of cyanocobalamin (vitamin B_{12}), 100 mg. of ferrous betaine, and 75 mg. of concentrated liver extract, was given a therapeutic trial in 35 patients with pernicious anemia who received this preparation orally. Eleven of the 35 patients were given large doses of 3 to 6 tablets of the preparation daily. In 9 of the 11 patients a reticulocyte crisis was produced in a normal manner, at the 3rd day as the earliest and at the 8th day as the latest; it was possible to follow in a regular manner the normalization of the Price-Jones curve in the course of the treatment. The drop in the iron level of the serum was also observed in a regular manner; complementary treatment with iron was even required occasionally. A normal vitaminemia was obtained in 6 of the 11 patients. These results compared favorably with those obtained in 64 patients with pernicious anemia, who were treated in the classic manner by the parenteral route, 42 of them receiving injections of cyanocobalamin, 8 receiving folic acid, and 14 receiving liver extracts. The oral treatment was ineffective in only 2 patients; in one of them a reticulocyte crisis could not be obtained either by injections of cyanocobalamin, and in the other such a crisis was obtained by additional treatment with folic acid.

The observations on the 11 patients treated orally suggested the use of the combined preparation of intrinsic factor and cyanocobalamin as a routine oral treatment for pernicious anemia. Twenty-four patients with pernicious anemia, who for 3 years did not have any recurrence of anemic or neurological type while receiving maintenance treatment with cyanocobalamin by the parenteral route, were given substitute treatment with the combined preparation of intrinsic factor and cyanocobalamin by mouth. There was no change notable in the red blood cell count of these patients. The average number of red blood cells (4,670.000 per cubic millimeter) observed in the patients receiving oral treatment was nearly identical with the number (4,550,000) observed in 28 patients treated by the parenteral route and reported on by other workers. The cyanocobalamin blood level of the patients given oral treatment with the combined preparation remained definitely reduced (an average of 0.175 mg. per cubic centimeter). There was no difference between this level and that obtained with other preparations. The new preparation, as a rule, was well accepted by the patients.

Severe Neurological Manifestations in Four Children Receiving Compazine (Prochlorperazine). J. T. Jabbour, J. A. Sheffield and J. M. Montalvo. J. Pediat. 53:153-159 (Aug.) 1958 [St. Louis].

Prochlorperazine (Compazine) is a relatively new antiemetic and tranquilizing agent, belonging to the large group of phenothiazine derivatives, of which chlorpromazine (Thorazine) and promazine (Sparine) are also members. The chemical name is 2-chloro-10-[3-(1-methyl-4-piperazinyl) propyl] phenothiazine. It was introduced into practice as an antiemetic and tranquilizing agent considered to have somewhat fewer toxic and side-effects than certain other ataractic agents. The authors present 4 children, ranging in age from 14 months to 5½ years, in whom Compazine produced a dramatic and characteristic clinical picture, with the following striking features: marked drowsiness and lethargy; oculogyric crisis; retraction of the neck, at times with torticollis; trismus; opisthotonos; at times, flexor rigidity; and hyperreflexia. These manifestations appeared suddenly in attacks that lasted from a few seconds to 2 hours and were followed by lucid intervals with normal neurological examination; there was a marked tendency to repeated attacks over a period of several hours. No permanent neurological damage was detected in any of the 4 children who were followed for a period of one month after their reactions. Two children received the drug on prescription for its antiemetic effect. The drug was given to another child for its tranquilizing effect in order to facilitate the intravenous administration of fluids. The 4th child accidentally ingested the drug. The amount given was clearly excessive in 2 cases and unknown in 1. However, the severest reaction of all occurred in the child who received the usually recommended dosage.

The Use of Trypsin in the Therapy of Tuberculous Lymphadenitis and Tuberculous Fistulae. C. Rapoport. Dis. Chest 34:154-161 (Aug.) 1958 [Chicago].

The author reports clinical observations made between 1951 and 1957 on 6 girls and 2 boys, ranging in age from 8 to 13 years, and on a 33-year-old man, all of whom had been admitted to the Malben Tuberculosis Hospital in Israel. Seven of the children had tuberculous lymphadenitis, a 10-year-old girl had tuberculosis in portions of the sternum, and the man had tuberculous fistulas under the right clavicle with involvement of the first rib on the right side. Only those patients were selected for trypsin therapy in whom unequivocal evidence of the tuberculous causation of the lesions was present and who did not improve despite prolonged treatment with other antituberculosis drugs. Bacteriological studies (for Koch's bacillus), routine blood studies, urine examinations, liver function tests, electrocardiograms, and biopsies were performed at the start, during, and at the end of treatment, and for each patient roentgenograms were obtained of the neck, chest, vertebral column, and appropriate bones.

The patients received pure crystalline trypsin in sesame oil, 5 mg. daily in 2 divided doses for 6 weeks. The drug was administered intramuscularly in combination with one or more of the following: streptomycin, tetracycline, isoniazid (Rimifon), and aminosalicylic acid (PAS). In some patients the treatment was continued daily for 6 months, with an additional course of trypsin being given for 3 weeks at the termination of the 6-month period. No side-effects were noted during the treatment. Several patients obtained clinical healing within 3 to 6 weeks, as evidenced by a marked decrease in the size of the lymph nodes, disappearance of these nodes, closure of the fistulas, and scar formation. In those with bone tuberculosis the lesions healed more rapidly. From a histopathological point of view all the biopsies performed showed either marked improvement of the microscopic picture or evidence of complete healing. The rich deposition of collagen in healed lesions was noteworthy. Biopsy specimens obtained from lymph nodes at the end of treatment were negative on smear, culture, and guinea-pig inoculation for Koch's bacillus. Trypsin administered together with antibiotics or antibacterial agents appears to be the treatment of choice for tuberculous lymphadenitis, and tuberculous fistulae secondary to the lymphadenitis, and for bone tuberculosis.

Haemorrhagic Thrombocythaemia: Report of Two Cases Treated with Radioactive Phosphorus. J. R. Fountain. Brit. M. J. 2:126-130 (July 19) 1958 [London].

Although bleeding accompanying thrombocytopenia is commonly seen in hospital practice, the association of hemorrhage and thrombocythemia is extremely rare, only 30 cases having been reported in the literature. Bleeding most commonly occurs from the nose and the alimentary tract; bruising is not uncommon; purpura is rarely observed; blood loss invariably results in a hypochromic anemia; and all cases show a raised platelet count and leukocytosis. Thrombotic episodes are not uncommon and are presumed to be a function of the increased number of platelets, although the exact mechanism is unknown. The bleeding time is sometimes prolonged, the remaining tests for hemostatic function being normal. Hemorrhagic thrombocythemia is usually associated with other myeloproliferative disorders or splenic atrophy. It may follow splenectomy, as was the case in one patient described in this article, and it is rarely primary in that it is unassociated with other pathological processes, as was found in the other patient reported by the authors. In both patients the platelet count returned to normal and the bleeding ceased after administration of radioactive phosphorus ($P.^{32}$).

A New Orally Effective Long-Acting Ganglion-Blocking Agent for Hypertension (189c56). S. Locket. Brit. M. J. 2:74-78 (July 12) 1958 [London].

The compound 189c56 is a preparation that was developed as the result of earlier pharmocological investigations of ganglion-blocking agents for use in hypertensive states. Compared with pentacynium methylsulfate, to which it is chemically related, about twice the dose of the active cation of 189c56 is required by subcutaneous or intravenous injection to produce a commensurate fall in blood pressure. The initial studies indicated that 189c56 produces hydrodynamic changes and effects on renal function comparable to those of pentacynium, and it was possible to identify 189c56 in urine many days after the last therapeutic dose. Within the dose range of 200 to 1,250 mg. administered daily by mouth, it was possible to produce prolonged and marked hypotension in every patient receiving the salt 189c56 bis-methylsulfate trihydrate. The initial dose was on the order of 200 mg., and this was increased by 50 mg. every day until an appreciable hypotensive effect was obtained. Once a satisfactory drug level was reached—and this level was quite critical—the degree and duration of hypotension achieved showed very little variation. Where the maintenance dose was in the range of 300 to 1,250 mg., a reduction of 25 to 50 mg. reduced the clinical effect considerably, and, conversely, an increase of the same magnitude converted a moderately severe hypotensive effect into a marked and prolonged hypotension.

Dryness of the mouth was noticeable with larger doses, although gastric emptying was unimpaired. Disturbance of vision occurred, as with other ganglion-blocking agents, and was usually insignificant and readily alleviated with physostigmine or pilocarpine. The severity of hypertension did not influence the drug schedule, although it was noticed that younger patients required heavier maintenance doses, as did patients exhibiting renal insufficiency. Disturbances of bowel motility, constipation, urine retention, and ileus were conspicuously absent. One patient, who when first seen had considerable renal impairment, showed a marked improvement in his hypertensive state and renal function. Another patient died of uremia, although his blood pressure had been adequately controlled. Of the 2 other patients with impaired renal function, one has shown a progressive deterioration in renal function in spite of an initial marked improvement in general condition, while the condition of the other has improved, the blood urea level falling steadily to less than 30 mg. per 100 cc. With an effective reduction in blood pressure, these patients have shown a reversal of retinal changes, alterations in the electrocardiogram to a more normal tracing, reduction in heart size, and amelioration of many disturbing symptoms, such as paroxysmal nocturnal dyspnea and angina on effort. No significant effect was elicited upon duration of action of the orally administered drug, size of the dose, time of onset of symptoms, or hypotension by the considerable variation in constitution of the diet. No significant potentiating action of chlorothiazide was demonstrable.

Hematologic Complications Arising During Ristocetin Therapy: Relation Between Dose and Toxicity. E. J. Gangarosa, N. S. Landerman, P. J. Rosch and E. G. Herndon Jr. New England J. Med. 259:156-161 (July 24) 1958 [Boston].

Ristocetin is a new antimicrobial agent, a lyophilized preparation representing 2 antibiotics, ristocetin A and ristocetin B. These components have been isolated from the fermentation broth of the Actinomycete species, Nocardia lurida. Advantages ascribed to ristocetin include low toxicity, lack of development of resistant organisms, and absence of cross resistance to other antibiotics. The authors review the clinical experience with ristocetin at the Walter Reed Army Hospital, Washington, D. C., and the U. S. Naval Hospital, Bethesda, Md. Of a total of 14 patients, 3 were treated terminally and died within 36 hours; another was given the medication for only 1 day and was subsequently treated with a different antibiotic. In 8 of the remaining 10 patients, complications developed during the course of ristocetin therapy. The other 2 patients were adult males who had staphylococcic pneumonia that responded dramatically to ristocetin, with complete resolution and without laboratory or clinical evidence of complications. In addition to routine hematological studies, the platelet count was followed carefully in 1 of these patients before, during, and after therapy, and no platelet depression was noted. The dose in these 2 cases did not exceed 25 mg. per kilogram of body weight per day.

Ristocetin in each of the 8 patients in this report was administered intravenously, dextrose being used as a diluent. Hematological complications developed in all 8 patients, and 3 of these had acute thrombocytopenia. Severe bleeding, which accompanied thrombocytopenia, contributed to the deaths of 2 patients. In the third patient with thrombocytopenia there was a prompt return of the platelet count to normal after the ristocetin dose was reduced from 50 to 33 mg. per kilogram of body weight. Blood examinations, including platelet counts, should be made regularly in patients receiving ristocetin. Furthermore, the drug should be used only in hospitalized patients to facilitate early recognition of complications and prompt treatment. Ristocetin therapy should be undertaken cautiously in patients with impaired renal function. The complications observed in this study are best explained by a peripheral direct toxic effect of ristocetin. Such complications may be reversible when recognized promptly and the drug withdrawn or the dose reduced. The authors feel that the demonstrated effectiveness of ristocetin in difficult enterococcic and staphylococcic infections, found to be resistant to other antibiotics, justifies its continued use.

Palliative Treatment of Cancer of the Genital Organs with Testosterone Enanthate. C. Giornelli. Minerva med. 49:2351-2354 (June 13) 1958 (In Italian) [Turin, Italy].

Twenty women with cancer of the genital organs were treated with testosterone enanthate after receiving a course of radium therapy and roentgenotherapy. Ten patients had cancer of the portio vaginalis uteri, League of Nations classification 3. The initial total dosage of testosterone enanthate, varying from 500 to 750 mg., was divided into 2 or 3 equal doses and administered every other day. The total maintenance dosage of 2,000 mg. was divided into 20 equal daily doses. This therapy produced improvement in the general state of the patients' health and in their appetite. Decrease in pain was not prompt, but it was lasting. The neoplastic masses had increased in size at the end of the treatment in all the patients.

Five patients had cancer of the portio vaginalis uteri, League of Nations classification 4. The initial total dosage of 1,000 mg. of testosterone enanthate was divided into 4 equal doses, which were administered every other day. The total maintenance dosage of 3,000 mg. was divided into 30 equal daily doses, with a drug-free period of 15 days after 20 days of therapy with the maintenance doses. This therapy produced slight improvement in the general state of health and in body weight and a decrease in pain. Gynecologic examination made 2½ months after discontinuance of drug therapy revealed larger neoplastic masses than at the onset of therapy in 2 patients; these 2 patients died afterward.

Three women had an inoperable cancer of the corpus uteri. The total dosage of testosterone enanthate, consisting of 2,500 mg., was administered in 2 courses lasting 15 and 10 days respectively. Testosterone enanthate brought about improvement in the general state of health and a decrease in pain. Consequently, the dosage of analgesic drugs which had been given to the patients was gradually decreased until it was nil. Two examinations, made 2 and 4 months after discontinuance of drug therapy, confirmed the persistence of the patients' improved state of health, appetite, body weight, and psychic state. Gynecologic examination revealed an unchanged state of the neoplastic masses.

Of the remaining 2 patients, one had a cancer of the vulva, with diffusion into the vagina and rectum and with bilateral inguinal metastases. She had received a course of roentgenotherapy. The initial total dosage of 1,000 mg. of testosterone enanthate was administered in 4 equal daily doses. The total maintenance dosage of 3,100 mg. was divided into 31 equal daily doses. The patient's state of health remained unchanged during the drug treatment, except for a slight improvement in appetite and in the psychic state. She died 5 months after discontinuance of drug therapy. The last patient, who was 47 years of age, underwent a Wertheim type of operation for carcinoma of the portio vaginalis uteri, classification 3, 8 months before the onset of chemotherapy. She was well for 6 months, after which intense pain in the lumbar region reappeared. The patient was given irradiation therapy, followed by treatment with testosterone enanthate in a total dosage of 2,300 mg. Improvement was evident 15 days after the beginning of this therapy, but deterioration began 3½ months later.

Clinical Evaluation of 6-Chloropurine in Leukemia of Adults. R. R. Ellison, D. A. Karnofsky and J. H. Burchenal. Blood 13:705-724 (Aug.) 1958 [New York].

Thirty patients, between the ages of 15 and 72 years, with acute leukemia were treated with 6-chloropurine. The bone marrow was predominantly or completely blastic in 14 of them. Five patients had acute granulocytic leukemia, and 11 had either acute granulocytic, myelomonocytic, or monocytic leukemia. Unless gastrointestinal side-effects necessitated diminishing the dose, 1 Gm. of 6-chloropurine was given daily as long as the total leukocyte count was stable or was falling slowly. If a rapid decrease occurred, the administration of the drug was discontinued temporarily and was started again as the count stabilized. Treatment was usually stopped temporarily when marrow cellularity was less than normal, as judged by the appearance of the smear and the aspirate, during the course of administration of the drug. Transfusions, intravenously administered fluids, and antibiotics were given when indicated by the clinical status of the patients. Three of the 30 patients had complete remissions, and 8 had partial remissions. The average time necessary for appearance of marrow remission was 8.1 weeks. In all 11 patients who had complete or partial remissions, a period of marrow hypocellularity preceded the occurrence of remission. The total period of response lasted from 4 to 46 weeks (average 18.3 weeks). In 6 patients who showed remissions, treatment was continued throughout the period of remission, and, therefore, relapse occurred during the treatment. Increasing the dose at the time of relapse in 2 patients produced no further response. In 4 other patients, 6-chloropurine was withdrawn because of leukopenia with a hypocellular marrow, and its administration was not started again until relapse occurred. Only one patient showed a second response. Administration of the drug was discontinued after 8 months of almost continuous administration in one patient because of severe anorexia and nausea. When this patient subsequently relapsed, 2 courses of 6-chloropurine therapy were given without beneficial effect.

Adequate courses of 6-chloropurine were given to 4 patients with chronic granulocytic leukemia. Three of these 4 patients responded to 6-chloropurine. Slight objective improvement was noted in 4 patients with lymphomas who were treated with 6-chloropurine, but improvement appeared only during the period of hematological toxicity when therapy had to be discontinued. A high incidence of jaundice was noted in the patients with acute leukemia and in the other patients treated with 6-chloropurine, but it is difficult to relate the occurrence of jaundice definitely to the therapy. While 6-chloropurine appears to be slightly superior to 6-mercaptopurine in acute leukemia in adults, the pattern of response would indicate that these agents have a similar mechanism and range of therapeutic activity.

Complementary Therapy of Cancer of the Cervix Uteri with Very High Doses of Testosterone Enanthate. M. Rossi, *I. Siliotti*, M. Giaquinto and others. Minerva med. 49:2355-2363 (June 13) 1958 (*In Italian*) [Turin, Italy].

Eight hospitalized patients with cancer of the cervix uteri, classifications 2 and 3, were each treated with 10 Gm. of testosterone enanthate, divided into 20 equal daily doses and administered intramuscularly. At the end of the treatment the following variations were observed: decrease in the erythrocyte sedimentation rate; increase in the azotemia level; decrease in the glycemia level; and slight decrease in the serum albumin level. The alpha-1 globulin level remained unchanged, but fractions of serum globulin alpha-2, beta, and gamma, increased slightly in value. The total serum protein value showed a slight increase, although it had been above the physiological limit even before the onset of hormonal therapy. There were no significant changes in the hepatic and cardiovascular functions. A clear improvement in well-being, appetite, body weight, and physical strength and a decrease in pain were observed. On macroscopic examination, the color and consistency of the tissues in the tumorous regions seemed improved, although no changes in the shape or in the total size of the tumors were noted. On microscopic examination, the histological and histochemical features of all the neoplastic masses remained unchanged; there was, however, evidence of slight reaction of the host tissues against the tumors, consisting in cornification and in necrotic processes of these tumors. Diminution in the serum acid phosphatase level also took place.

Untoward side-effects in the administration of testosterone enanthate consisted in the manifestation of certain features of virilism and in an increased sense of libido. The clitoris increased moderately in size in 6 patients, considerably in 1, and insignificantly in 1 after the dosage had reached 5 Gm. in each patient. Lowering of the pitch of the voice, which was noticed by each patient herself but was imperceptible to other persons, developed in 3 women. These variations did not produce unfavorable psychosensory changes in the patients. The patients were advised to continue with maintenance doses of the hormonal therapy after discharge. The authors believe that administration of testosterone enanthate is a useful complementary procedure to radiotherapy for management of inoperable cancer of the female genital organs.

PATHOLOGY

Importance of Staphylococcus Aureus in Pneumonia in the 1957 Epidemic of Influenza. A. L. Robertson, J. P. Caley and J. Moore. Lancet 2:233-236 (Aug. 2) 1958 [London].

The authors report on 140 patients, between the ages of 11 and 80 years, with pneumonia who were admitted to the City General Hospital in Sheffield, England, during the peak of the epidemic caused by the Asian variety of influenza, type A, virus in September and October, 1957. Results of bacteriological examination of sputum and autopsy specimens revealed that Staphylococcus pyogenes var. aureus was isolated from 38 (27%) of the 140 patients, Diplococcus pneumoniae from 12 (9%), and Hemophilus influenzae from 5 (4%). Eighteen of the 38 patients with staphylococci died, a mortality rate of 47%. Sixteen of the 102 patients without staphylococci died, a mortality rate of 16%. The over-all mortality rate among the 140 patients was 29%. There was no clear sex difference in either group. The strains of Staph. pyogenes var. aureus obtained from 12 of the 18 patients who died were sensitive to chlortetracycline (Aureomycin), chloramphenicol, penicillin, streptomycin, erythromycin, and sulfonamides; the strains of Staph. pyogenes var. aureus obtained from the remaining 6 patients were resistant to chlortetracycline, penicillin, streptomycin, and sulfonamides and sensitive to erythromycin and/or chloramphenicol. There was evidence that 13 of the 140 patients were infected in the hospital with strains of Staph. pyogenes var. aureus which were resistant to penicillin, chlortetracycline, streptomycin, and sulfonamides.

The treatment of the fulminating staphylococcic infections is very difficult, because it is necessary to treat both the bacterial infection and the attendant pulmonary edema and peripheral circulatory failure. Fourteen such patients died within the first week of admission to hospital, and all had been treated in hospital with massive doses of antibiotics, including erythromycin and chloramphenicol. Despite this treatment antibiotic-sensitive strains of Staph. pyogenes var. aureus were isolated from 12 of the patients at autopsy. In contrast, the less severely affected patients responded well to antibiotics, and those infected in the hospital with antibiotic-resistant strains responded well to the antibiotics indicated by the in vitro sensitivity tests.

Atherosclerosis and the Serum Mucoprotein Levels of the Australian Aborigine. C. J. Schwartz and J. R. Casley-Smith. Australian J. Exper. Biol. & M. Sc. 36:117-120 (April) 1958 [Adelaide].

The first of 3 groups of normal male subjects investigated was composed of 22 full-blooded male Pintubis living nomadically in the Western Desert of Central Australia and consuming essentially a simple bush diet. There were 21 full-blooded male Australian aborigines of mixed tribal origins in the second group, whose dietary and living habits more closely resembled those of the white people in the area. The third group consisted of 38 Australian males of European descent. These 3 groups, all of whom were healthy, normotensive, and without any clinical evidence of atherosclerotic disease or any other condition known to affect the serum mucoprotein levels, had a mean age of 32, 36, and 37 years respectively. The mean serum mucoprotein level of nomadic tribal Pintubis was found to be considerably lower than the mean level of the urban group of full-blooded detribalized aborigines and the mean level of a group of normal white Australians of comparable age. The latter differences are considered highly significant with p values less than 0.001. The differences between the detribalized aborigines and the white Australian controls is not significant. Atheroma is not found with either great severity or frequency in the Australian aborigines in contrast to the almost universal finding of extensive atherosclerosis in Australians of European descent. The fact that the urban group has a higher serum mucoprotein level than the nomadic Pintubi group precludes the possibility of an ethnic constitutional factor to account for the difference between aborigine and white Australian.

Natural History of Multiple Myeloma Before Radiological Evidence of Disease: Memorial Fund Lecture. E. F. Osserman. Radiology 71:157-174 (Aug.) 1958 [Syracuse, N. Y.].

In an attempt to support the theses that radiographically evident multiple myeloma usually has already progressed to an advanced stage and that the diagnosis of a proliferative disorder of plasma-cell origin is frequently possible by biochemical techniques before roentgen-ray changes are demonstrable, the author reports on 18 men and 6 women, between the ages of 46 and 82 years, with "dysproteinemia of the myeloma type." Serum protein electrophoresis revealed that the serum of these patients contained an abnormal protein at a time when there was neither clinical nor roentgenologic evidence of disease. The patients were followed for periods ranging from a few months to 3 years. Clinically and radiographically evident skeletal damage and disease patterns consistent with a diagnosis of myelomatosis developed in 2 of the 24 patients, and 1 of them died. Four additional patients died of causes other than those which could be directly attributed to primary plasma-cell proliferative disease. Autopsy was performed on 2 of these 4 patients, and microscopic examination revealed diffuse plasma-cell infiltration of the skeletal system, but no gross evidence of skeletal damage. Careful clinical, roentgenologic, and electrophoretic studies have been continued in the 18 surviving patients.

The concentration of abnormal protein has either remained constant or shown an increase. In none of these patients has a spontaneous decrease or a disappearance of the dysproteinemia been observed.

The patients included in this study had failed to satisfy the diagnostic criteria for one or another of the clinical variants of primary plasma-cell proliferation when they were initially examined. Patients with clinically evident para-amyloidosis, such as those with documented lymphatic dyscrasias and myeloma-type dysproteinemia, were specifically excluded, but it is quite probable that some of the patients still under observation will ultimately display one or another of these clinical patterns in which bone involvement is not a significant feature. The routine application of the technique of serum protein electrophoresis may, however, help in defining the earlier stages of plasma-cell proliferative disease, but it must be borne in mind that it is only after serum concentrations of 200 to 300 mg. per 100 cc. of an electrophoretically homogeneous protein constituent have been established that electrophoresis will ascertain its presence. In about 15% of patients with known myelomatosis there is no electrophoretically demonstrable dysproteinemia. These patients do, however, show an electrophoretically characteristic dysproteinuria. Possibly, routine urinary protein electrophoresis in patients with unexplained proteinuria might identify some of the cases of myelomatosis in an early stage.

Pathogenetic Importance of the Thoracic Portion of the Vertebral Column. H. Kamieth. Arch. orthop. u. Unfall-Chir. 49:585-606 (No. 6) 1958 (In German) [Munich, Germany].

The authors made a roentgenologic study of the thoracic spine in 100 patients with roentgenologically proved ulcers of the stomach and duodenum. The group included 83 men and 17 women. Sixty-one men and 11 women had duodenal ulcers; 20 men and 3 women had gastric ulcers; and the other 5 patients had both gastric and duodenal ulcers. Answers were sought to the following questions: 1. What morphologic and functional changes can be observed in the thoracic portion of the vertebral column? 2. What connections exist between the morphologic changes and the disturbances in the static functions? 3. Is it possible that the morphologic and functional changes will act as pathogenetic factors? The majority of patients (86 of 100) had lateral curvature scoliosis of the thoracic portion of the vertebral column, which, however, was essentially postural, since it could be compensated by forward flexion in two-thirds of the male patients and in about one-half of the female patients. A tendency to gradual fixation of the postural scoliosis was demonstrated by its appearance when a roentgenogram was made with the patient in the supine position. The convexity of the scoliosis was toward the right side in 60 of the patients and toward the left side in 21, and the remaining 5 patients had an S-shaped scoliosis. The percentile distribution of right-sided and left-sided scolioses coincided with the percentages of duodenal and gastric ulcers. All the scolioses involved the vertebral segments corresponding to the stomach and duodenum, that is, T-6 to T-9. The scolioses were mild, some being so slight that they could hardly be differentiated from variations within the normal range.

Spasticity of the musculature of the back was present in all but 17 of the 100 patients. Moreover, almost 90% of all the patients had pathological changes on the intervertebral disks. These disk changes and their relationship to osteochondrosis of the vertebrae, to Schmorl's nodules, and to spondylitic processes are discussed. On the basis of diagrams the author explains the pressure, shifting, and rotational forces that are most important in the production of the functional changes in the intervertebral disks. Spatial infringement in the intervertebral disk canals seems to be of vital importance, and this contraction of the canals seems to be a complex process, in which morphologic and functional, as well as nerve root, changes may play a part. It has not been definitely proved whether these various space-infringing factors or disturbing influences act directly on the nerve roots or indirectly by way of stasis and edematous changes in the intervertebral disk canals. There is also a possibility that the ligamentous apparatus, as well as the disks at the nerve roots, play a part. Morphologic-osteogenic changes seem to be less important than functional-dynamic changes. At any rate processes in the vertebral column seemed to play a part in 90 of the 100 patients with peptic ulcers.

A Histochemical Evaluation of Carcinoma in Situ of the Cervix Uteri. R. E. L. Nesbitt and A. R. Stein. Surg. Gynec. & Obst. 107:161-168 (Aug.) 1958 [Chicago].

The present study comprises a histological and cytochemical appraisal of cervical tissue obtained from 42 patients with carcinoma in situ, admitted to the gynecologic service of the Albany (N. Y.) Hospital during the 8-year period from 1947 to 1955. The diagnosis was established by cervical biopsy in 31 cases, the lesion being identified in the remaining 11 cases in uteri surgically removed because of leiomyoma, adenomyosis, diffuse pelvic endometriosis, and chronic salpingitis. In addition to the material obtained by biopsy, the uteri of 26 of these same patients were subsequently available. The periodic-acid Schiff procedure proved to be the simplest and most reliable of the staining techniques for demonstrating the basement membrane beneath the cervical epithelium. The presence of intracytoplasmic glycogen in normal cervical epithelial cells and its absence in neoplastic cells is the biochemical basis of Schiller's iodine tinctorial test. The periodic-acid Schiff method was useful not only in identifying the basement membrane but also in determining objective invasion, as well as in evaluating the degree of maturation and differentiation of cervical epithelium. Carcinoma of the ectocervix is a distinct entity characterized by atypical basal-cell hyperplasia with a failure of cell maturation. This lesion when present in the endocervix results from reserve-cell hyperplasia with absolute failure in differentiation as well as in maturation. Basal-cell hyperactivity, atypical hyperplasia, and bizarre forms of squamous-cell metaplasia can readily be differentiated from carcinoma in situ by determining the stainability of the abnormal epithelium with the periodic-acid Schiff procedure and noting the degree and extent of cellular atypia. Histological variants in the form of basal-cell hyperplasia and atypical hyperplasia with delayed or irregular maturation in the intermediary epithelial zone were found infrequently. The latter lesion is predominantly a prickle-cell type and appears in both the ectocervical and the endocervical regions. The authors attempt to correlate the cellular changes and the biological characteristics of carcinoma in situ with a view toward standardizing the diagnostic criteria.

Immunity in Experimental Tuberculosis. B. K. Acharya, F. M. Sullivan and J. M. Robson. Am. Rev. Tuberc. 78:203-225 (Aug.) 1958 [New York].

The method of immunizing mice with an intracorneal or intradermal injection of mycobacterium tuberculosis, and challenging the animals by a subsequent intracorneal inoculation, was used by the authors to study quantitatively the development of immunity to tuberculosis. The immunity resulting from a previous vaccination was assessed by the development of macroscopic lesions and the extent of bacillary multiplication in the challenged eye. It was found that some degree of immunity could be shown with a challenge given 48 hours after vaccination and that the immunity gradually increased to a maximum about 1 month after vaccination. At this stage a small inoculum (about 500 organisms) underwent no multiplication whatever in the challenged eye. Immunity sufficient to prevent the occurrence of any macroscopic lesions in challenged eyes was observed up to 13 months after vaccination, the longest period studied. The introduction of a larger challenge dose in immunized animals was followed by bacterial multiplication and the production of a macroscopic lesion; i. e., the larger challenge did overcome the immunity, although the extent of the multiplication lagged behind that observed with a similar dose of bacilli in nonimmune animals. Detailed microscopic investigation showed that, when a large inoculum overcame immunity, this was not due to insufficient phagocytic invasion and that under thees conditions intracellular multiplication of organisms, with ensuing destruction of the cells, did occur. The production of immunity with bacilli killed by various methods then was investigated. The best results were obtained with phenol-killed organisms which, in large doses, produced an immunity almost comparable with that seen with live organisms.

RADIOLOGY

Intravenous Cholangiography: An Appraisal. I. S. Goldenberg and A. J. Kummer. Connecticut M. J. 22:585-591 (Aug.) 1958 [New Haven].

Fifty-seven cholangiograms were done on 54 patients during the period from 1954 to 1957. Cholografin was utilized in all these studies, except in one patient in whom an additional study was done with Intrabilex. All the studies were completed without incident save for a 55-year-old woman in whom a probable sensitivity reaction occurred. In 29 patients intravenous examination was necessary to evaluate upper abdominal symptoms after cholecystectomy. Symptoms suggestive of biliary tract disease were present in 10 patients in whom oral cholecystograms with Telepaque had been accomplished without visualization. In 18 patients both oral and intravenous methods were employed, because initial visualization with the oral technique had proved inadequate. It is of note that of 15 patients who failed to reveal visualization after single-dose and double-dose Telepaque administration 9 had good intravenous Cholografin visualization after oral and intravenous techniques, and in only one case was visualization better after oral Telepaque administration than after intravenous Cholografin. Three of the 7 patients presenting jaundice had the duct system visualized. Forty-two cholangiograms in which the biliary radicles were visualized were available for critical evaluation. Maximum concentration of injected material occurred in from 40 to 70 minutes in two-thirds of these patients, maximum density occurring in 3 patients in less than 40 minutes after injection and in 10 patients only after 70 minutes had passed. Of the total group of examinations done, 30 were interpreted as being normal insofar as visualization of the biliary system was concerned. Twelve studies demonstrated definite abnormalities, which included cholecystolithiasis in 6, choledocholithiasis in 2, and common duct obstruction in 2.

Only 10 patients in the present group had operative intervention after the intravenous cholangiogram. Pathology found at operation confirmed the intravenous study in 8 patients. In 5 patients in whom Cholografin studies revealed a cholecystolithiasis or choledocholithiasis, such stones were found at operation. An enlarged common duct was found at operation in 2 patients in whom it had been previously demonstrated, and in 1 patient in whom no stones were seen on intravenous study none were found at operation. Two patients had no apparent stones by roentgenography, but at operation they were found to have stones in the common bile duct and in the gallbladder. The authors consider intravenous cholangiography a good procedure but believe that it should be reserved for patients who are symptomatic and in whom all other methods of visualization of the biliary tract have failed, because, despite the infrequency of reactions to the injection medium, deaths have been reported.

ANESTHESIA

Hypothermia in Thoracic and Thoracoabdominal Surgery: Use of Light Cooling as an Adjunct to Anesthesia in Poor Risk Patients. L. A. Brewer and E. L. King. Am. J. Surg. 96:137-150 (Aug.) 1958 [New York].

The authors report on 18 patients, between the ages of 34 and 77 years, who were subjected to thoracic and thoracoabdominal surgery. Six of these patients had bronchogenic carcinoma; 6, carcinoma of the esophagus; 1, bilateral pulmonary tuberculosis; 1, chronic emphysema and calcification of the pleura; 1, benign stricture of the esophagus; 1, malignant teratoma of the mediastinum; 1, teratoma of the epicardium; and 1, multiple fractures, ruptured diaphragm, and sepsis. These patients were considered poor risks for conventional normothermic anesthesia, and extensive thoracic and thoracoabdominal surgery was performed on them with the aid of light hypothermia, i. e., the patient's body temperature was lowered to 33 to 30 C (91.4 to 86 F) by packing with ice. Premedication included small doses of barbiturates, meperidine (Demerol) hydrochloride, and atropine or scopolamine. The patients represented about 5% of this type of patients operated on by the authors during the same period. The indications for hypothermia were as follows: (1) cardiac conditions, including previous infarction, auricular fibrillation, myocardial insufficiency, and cardiac failure; (2) respiratory conditions, including low maximum breathing capacity and pulmonary reserve from various causes resulting in an actual or threatening hypoxic state; (3) generalized arteriosclerosis; (4) hepatic or renal insufficiency; (5) trauma; and (6) infection.

The most striking finding during surgical intervention was a bright red oxygenation of the blood and a slow, firm cardiac beat. A light anesthesia was maintained with high-oxygen concentration by means of small amounts of ether and/or nitrous oxide. Three patients, all undergoing esophagectomy, did not survive the postoperative period; death was caused by cerebrothrombosis in 1 patient on the 3rd postoperative day, by a cerebral embolus in 1 on the 5th postoperative day, and by delayed cardiovascular collapse in 1 on the day after surgical intervention. The advantages of light hypothermia appeared to be better oxygenation of the blood in the course of the surgical intervention, need of only small amounts of anesthetic for long operations, and less stress of operation. The disadvantages were low blood pressure during phases of surgery, cardiac collapse on mediastinal dissection, and delayed postoperative shock or cardiovascular collapse. With the light hypothermia used in this group of patients, ventricular fibrillation did not occur in any of the patients. Temperatures below the levels used are dangerous with present-day methods and probably unnecessary. Children and young and middle-aged adults tolerate light hypothermia quite well. Older patients (above 60 years of age) show more cardiac reflex sensitivity in the course of the operation and a greater incidence of delayed postoperative shock. The final place of light hypothermia cannot be stated at present. Because of the favorable results in these patients, which could not have been duplicated with the aid of normothermic anesthesia, further trial is definitely indicated.

PHYSIOLOGY

Hyperexcitability of the Pulmonary Sensory Endings in Asthmatic Subjects: Its Measurement, Characteristics, Causes, and Role as a Reflex Asthmogenic Factor. R. Tiffeneau. Presse méd. 66:1250-1252 (July 12) 1958 (In French) [Paris].

Acetylcholine administered by the respiratory route in aerosol form has a twofold action: 1. It excites the pulmonary motor effectors (the smooth muscles of the bronchi and the vessels, and the bronchial glands), bringing about bronchoconstriction which alters pulmonary ventilation and may lead to asthma. 2. It excites the pulmonary sensory nerve endings, giving rise to laryngotracheobronchial sensations and sometimes causing a tussigenic reaction. These two methods of action, which are pharmacodynamically distinct, are opposed by two elective antagonists: (1) atropine, which prevents excitation of the motor effectors, and (2) pentamethonium and hexamethonium, which prevent excitation of the sensory nerves but have no antagonistic effect on smooth muscle excitation.

The second or sensory-nerve-excitation method of action was used in studying and measuring the excitability of the pulmonary sensory nerve endings in 105 patients with asthma. The inhalation of an aerosol containing 100 mcg. of acetylcholine per liter often leads to cough in normal subjects, whereas inhalation of one containing only 30 mcg. of acetylcholine rarely does so. The excitability of a patient in whom cough is produced by a concentration of 100 mcg. may therefore be regarded as normal, while that of one who coughs on inhaling a solution with a concentration of only 30 mcg. may be regarded as abnormal. Application of this criterion to the findings obtained in these patients showed that the excitability of the pulmonary sensory nerve endings was greatly increased in 25 (23.8%) and moderately increased in 39 (37.1%). Acute diseases of the lungs, which are frequent in asthmatic subjects, probably help to increase the excitability of the pulmonary sensory nerve endings. Ordinary bronchitis and even a simple cold often cause a temporary increase in this excitability in both asthmatic and normal subjects. Moreover, the excitability of the sensory nerve endings tends to increase as the asthmatic condition worsens, as shown by the correlation between an increase in cough, expectoration, and sensitivity to exogenous irritants and a diminution in pulmonary function, on the one hand, and an increase in excitability, on the other.

The hyperexcitability of the pulmonary sensory nerve endings may become an asthmogenic factor by giving rise to a bronchoconstrictive reflex. Cold air and irritating particles carried by the wind serve to precipitate this bronchoconstrictive reflex. Study of the dyspneic manifestations of asthma seems to show that there is a similarity between irritating particles and allergenic particles: both are carried by the air, and both are an indirect cause of bronchoconstriction, the first through the intervention of a reflex, the second through that of a mediator (histamine). Allergenic aggression predominates in recent forms of asthma; irritating aggression, in asthma of longer duration. The two factors, however, may occur together, producing mixed dyspneic reactions as a result of the twofold irritant and allergenic effect on the lungs.

PUBLIC HEALTH

Preliminary Report on Mass Vaccination of Man with Live Attenuated Poliomyelitis Virus in the Belgian Congo and Ruanda-Urundi. G. Courtois, A. Flack, G. A. Jervis and others. Brit. M. J. 2:187-190 (July 26) 1958 [London].

The authors report on 244,596 inhabitants of the Belgian Congo and Ruanda-Urundi, of both sexes and all ages, who were vaccinated during the years 1957 and 1958 in the course of trials with live attenuated Chat strain, type 1, poliomyelitis virus by the oral route. Of these 244,596 persons, 2,511 received, in addition, Fox III strain, type 3, of attenuated poliomyelitis virus. The virus pools representing each strain were tested for lack of virulence in rhesus monkeys injected intracerebrally and intraspinally and in chimpanzees injected intraspinally. None of the intracerebrally injected monkeys and intraspinally injected chimpanzees showed signs of illness. Some of the monkeys injected intraspinally with the undiluted material showed signs of poliomyelitis infection. For additional testing, aliquots of each pool were injected into rabbits, mice, and guinea pigs in order to rule out the presence of other viral agents, such as the Coxsackie viruses. Although the material was filtered through bacteria-retaining filters, rigid tests for bacterial sterility were completed before the virus pools were used in man. The efficiency of each virus preparation was finally checked by feeding the virus to a small group of infants and adults in the United States. These persons had no antibodies against the type of virus administered, and there was no reaction of any kind. This procedure made it possible to determine the minimum immunizing dose of the virus, which was $10^{3.7}$ TCD_{50} for nonimmune children and adults and $10^{5.0}$ TCD_{50} for infants less than one month old. The virus preparation was administered in either capsule or liquid form. The approximate minimum dose fed to each individual was $10^{5.3}$ TCD_{50} of each strain. Throughout the period of administration the container of virus suspension was kept at 4 C. Immunization of the total population of the community was decided on only if 12% or more of the serums collected were found to have no antibodies against a given type of virus. Since type 1 virus was incriminated in most outbreaks of paralytic poliomyelitis, including those in the Belgian Congo, it was decided to give priority to vaccination with attenuated Chat strain, type 1, virus wherever it was statistically feasible.

In 2 localities, Aketi and Stanleyville, no signs of illness were observed after administration of the 2 types of viruses, and in almost 100% of the vaccinated persons antibodies against the 2 types developed which were determinable in the serums. No illness, which could be attributed to vaccination, was reported by medical authorities in a third locality, the Ruzizi Valley, after mass vaccination trial of Chat strain, type 1, poliomyelitis virus. On recommendation of the Expert Committee on Poliomyelitis of the World Health Organization, this live virus was administered orally during 4 outbreaks of paralytic poliomyelitis at Banalia, Gombari, Watsa, and Bambesa in the Belgian Congo. After vaccination no more cases of paralysis were reported in these localities.

BOOK REVIEWS

Diagnostic Anatomy. By Weston D. Gardner, M.D., Associate Professor of Anatomy, Marquette University School of Medicine, Milwaukee. Cloth. $10. Pp. 376, with 20 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1958.

Diagnostic anatomy is a new concept in an anatomy textbook, and the author is to be congratulated on presenting this type of book. The object of the monograph is to link the book with the physical examination of the patient. It is felt that a correlated approach to certain aspects of regional gross and topographic anatomy, based on the techniques, sequence, and problems faced by the physician in the physical examination, should be helpful to the student or practitioner who wishes to reacquaint himself with the anatomic features of the body he examines. The book is well written and easy to read. The printing is excellent. The illustrations, which are by the author, are line drawings demonstrating the desired points. It is regrettable that there are not more of them. Although the author states that surgeons are generally more anatomy-conscious than other physicians because they are concerned with anatomic dissections, the monograph should be valuable even to a surgeon, but it should be particularly valuable for those practitioners who come in contact with the anatomic structure of the body less frequently than surgeons. The book should be valuable also to students, especially in their course in physical diagnosis.

The Esophagus: Medical and Surgical Management. By Edward B. Benedict, M.D., F.A.C.S., Assistant Clinical Professor of Surgery, Harvard Medical School, Boston, and George L. Nardi, M.D., F.A.C.S., Clinical Associate in Surgery, Harvard Medical School. Foreword by Edward D. Churchill, M.D., F.A.C.S. Cloth. $15. Pp. 390, with 124 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Place, Portman Sq., London, W. 1, England, 1958.

This is a Boston book from cover to cover. That is all to the good, since the authors are surgeons and teachers of surgery in the Massachusetts General Hospital and Harvard Medical School. With thoracic surgery well established, it is amazing what advances have been made in a short time. The chest used to be a *noli me tangere.* One felt rather proud to make a diagnosis of cardiac, pulmonary, or esophageal lessions that could be confirmed at autopsy. Although we are still clamoring for early diagnosis so that surgery can have a better chance for cure, surgical conditions in the esophagus are not yet brought to the attention of the surgeon soon enough. The authors rightfully insist that difficulty in swallowing is a primordial and highly important symptom of carcinoma, but both patient and physician speak of indigestion, spasm, and a "funny feeling" behind the breast bone. No better phrase has originated in this century than "cancer alert." Both x-ray and direct vision with the esophagoscope are helpful in making an early diagnosis. Hence, we now have a better idea of short esophagus, varices, strictures, foreign bodies, and ulcers. The literature on the esophagus is filled with monographs on various conditions, but, since it is difficult to look up so many references, having the etiology, symptoms, pathology, complications, and treatment all under one cover is a great help to the physician and especially the gastroenterologist. What to do must always require careful judgment. How to do it is well illustrated by the numerous and excellent drawings, photographs, and color plates in this book.

Reflexogenic Areas of the Cardiovascular System. By C. Heymans, M.D., Professor of Pharmacology, University of Ghent, Belgium, and E. Neil, M.D., D.Sc., John Astor Professor of Physiology, University of London, Middlesex Hospital Medical School, London. Cloth. $10. Pp. 271, with 89 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6, 1958.

The senior author of this book is a Nobel prize laureate and the discoverer of the chemoreceptor action of the carotid and aortic bodies. This book gives not only a critical evaluation of the physiology of the sinoaortic receptors but also a survey of cardiovascular reflexes in an attempt to correlate the latter with definite receptors characterized by anatomic localization and physiological function. Although the bulk of the work is based on the discussion of physiological investigations, the anatomic and embryologic basis is adequately covered. The problem of neurogenic hypertension (resulting from elimination of the sinoaortic receptors) is dealt with in a brief chapter. There is much material in this book of great value to investigators interested in cardiovascular physiology, respiration, and the neurophysiology of receptors. The text is well printed and provided with excellent illustrations, an extensive bibliography, and a short index. Since parts of the book are difficult to read, it is regrettable that there are no summaries. Criticism is frequently presented with unusual vigor. Certain data in the literature are found to be "exasperating."

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

The authors speak of the "illogicality" of an argument and say that even Claude Bernard "rashly concluded." On the other hand, with reference to his own work, the junior author writes (p. 184): "Recently Green and Neil (unpublished) have proved." These are unfortunate defects in an important book. They are mentioned because they are bound to weaken the trust in the arguments of the authors.

Neuropathology. By J. G. Greenfield, M.D., F.R.C.P., LL.D., and others. Cloth. $20. Pp. 640, with illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; Edward Arnold (Publishers) Ltd., 41-43 Maddox St., London, W. 1, England, 1958.

This admirable volume of neuropathology appeared shortly after the death of the senior author, who was one of the world's outstanding neuropathologists; it is a vade mecum for those who wish to work in this interesting area. The book is easy to read, and its style is especially attractive. Greenfield expended great care in presenting details. He brought neuropathology back to being primarily concerned with the nervous elements of the nervous system. There is often, in neuropathology, a temptation to be distracted from the consideration of the nervous elements. This distraction is engendered by the impressiveness of the changes in supporting tissues. Greenfield points out in the introduction to the first chapter that the changes in glial cells and the inflammatory changes are really only secondary and that the primary concern is what happens to the neuronal elements and their processes. This is an indication of clear thinking and putting first things first. This volume is well illustrated with gross and microscopic pictures. The illustrations are all black and white but are so vivid that one can not criticize the lack of colored photography. A minor criticism of the book is that the illustrations are numbered in a rather unusual fashion, so that one has to use some care in finding the proper illustration. This book should be of great value to all serious students of pathology or of the nervous system.

Religious Doctrine and Medical Practice. By Richard Thomas Barton, M.B., B.S., M.D. Foreword by Raymond B. Allen, M.D. Cloth. $3.75. Pp. 94. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

This book is "designed to provide a reference for questions of religious dogma as they pertain to the practice of medicine." The author had the advice of members of the religions about which he writes. Consequently it may be assumed that there are no gross errors of dogma or its application, but so short a book must necessarily be limited to a consideration of only a limited number of matters—those considered by the author to be of major importance. Religious principles are discussed with the religious interest of the patient in mind. The book will serve a useful purpose if it does no more than remind the physician or nurse that the patient may have religious obligations or wishes the observance of which will not interfere with, but on the contrary may aid, medical care. It should, however, not be accepted as an authoritative treatise for the interpretation of religious dogma. The book contains a brief readable history and a brief discussion of some of the principle doctrines and practices of Hinduism, Buddhism, Judaism, Islam, Bahai faith, Roman Catholicism, Christian Protestantism, Mormonism, Jehovah's Witnesses, Seventh-day Adventism, Disciples of Christ, Christian Science, and Unitarianism.

Obstetrics and Gynecology. By J. Robert Willson, M.D., Professor and Head of Department of Obstetrics and Gynecology, Temple University School of Medicine, Philadelphia, Clayton T. Beecham, M.D., Clinical Professor of Obstetrics and Gynecology, Temple University School of Medicine, Isador Forman, M.D., Clinical Professor of Obstetrics and Gynecology, Temple University School of Medicine, and Elsie Reid Carrington, M.D., Assistant Professor of Obstetrics and Gynecology. Temple University School of Medicine. Cloth. $10.75. Pp. 605, with 267 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1958.

This book is the outgrowth of a mimeographed summary of the contents of courses in obstetrics and gynecology given to third-year and fourth-year medical students. The authors wrote the book to occupy a place between the large encyclopedic textbooks and the synopses devoted to these subjects. In this book, the authors have tried to include the essentials of obstetrics and gynecology and in this have largely succeeded, but, as may be expected when four experienced teachers write one book and the amount of space devoted to each subject is limited, there is sketchiness and unevenness. There are 51 chapters, each of which has a list of references at the end. The illustrations are abundant and instructive. Many have been borrowed from books written by Willson and the late Paul Titus. The advice given throughout the book is excellent and conservative. This is to be expected, because all four contributors are authorities in their specialties. This book should appeal to medical students, interns, and residents as a handy reference book for detailed information about obstetrics and gynecology. General practitioners and surely specialists will have to use the larger textbooks.

QUESTIONS AND ANSWERS

SLEEPING POSITIONS OF CHILDREN

To the Editor:—*Please comment on the advantages and disadvantages of having infants and children, normal or with upper or lower respiratory infection, lie on the stomach (postural drainage) for short or long periods of time. Is there any possibility of deformation of the thoracic bony structures in these infants?*

P. E. Gauthier, M.D., Montreal, Canada.

Answer.—The majority of infants sleep on their stomachs routinely, as they seem to rest more comfortably in this position. Older children sleep in a variety of positions. Children of any age will sleep more comfortably on their stomachs when they have the ordinary upper and lower respiratory infections. It is thought that this is due to the benefits of postural drainage. During the acute phase of pneumonia and other more severe lower respiratory tract infections, children are usually more comfortable in a partial Fowler's position. Once the acute phase has passed and secretions become more of a problem than gas exchange, postural drainage seems to be helpful. There is no evidence that sleeping on the stomach will influence in any way the development of the thoracic cage. There have been some suggestions that this position may predispose to positional deformities of the lower extremities. However, most pediatricians, after watching many children grow perfectly normally, feel that there is absolutely no connection.

Answer.—The normal infant and child should be given the freedom to assume any position in recumbency, i. e., prone, supine, or on either side. There is no basis for the thought that such practice will contribute to "deformation of the thoracic bony structures." When lower respiratory infections prevail, coughing is a defensive mechanism. The prone position in this instance is a significant advantage for drainage. The duration of such infections is usually not prolonged, and the time spent in the prone position does not promote the development of thoracic deformities. The incidence of tuberculosis of the spine in childhood is now very low. When present, recumbency is still indicated for a few months. For alternate hours the patient necessarily remains in the prone or supine position in some form of apparatus to restrict motion of the spine. In such cases there is a tendency for the thorax to lose its normal contours, i. e., the anteroposterior diameter may become less and the transverse diameter proportionately increased. Such a change may be retarded or prevented by the use of anteroposterior plaster shells.

BROMHIDROSIS

To the Editor:—*A 55-year-old man says his wife, and apparently several other persons, have noticed a peculiar odor over his forearms, hands, and shoulders. This is not a matter of personal cleanliness, as the odor may be apparent immediately after bathing. The odor has been described as fishy, musty, and like that of sardines or lutfisk. He has been examined exhaustively, and nothing of note has been found. Liver and renal function are both adequate. When the odor is present, it usually persists several hours and fades gradually.*

William A. O'Brien, M.D., Minneapolis.

Answer.—Bromhidrosis is the name applied to excretion of malodorous perspiration. This may resemble many of the unpleasant odors encountered in nature. Offensive odors may be noted in certain systemic diseases associated with excessive perspiration and in generalized dermatoses in which there is an admixture of scales, crusts, pus, bacteria, and necrotic material. Another form is exogenous in origin and is due to the ingestion of certain drugs and foods. In such instances, the use of garlic, onions, and other seasonings should be avoided. Perhaps the "fishy" odor in this patient is suggestive of the causative factors, and he should avoid the ingestion of all fish and seafoods. The normal perspiration, both exocrine and apocrine, is devoid of any strong odor. According to Shelley and others (*A. M. A. Arch. Dermat. & Syph.* 68:430, 1953), the action of bacteria on apocrine sweat produces the olfactory changes. In such instances, the odor can be prevented by hexachlorophene for as long as 18 hours. In one case, famous in dermatological annals, such an offensive odor in a patient was found to be due to a ring that he was wearing and elimination of the ring resulted in a permanent cure. The unpleasant odor may or may not be associated with hyperhidrosis. The treatment in this patient should be directed against bacteria with use of detergents containing hexachlorophene, and application of anhidrotics (such as aluminum chloride) and avoidance of malodorous ingestants (fish) should be tried.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

BLOOD EXAMINATIONS WITH OXALATED BLOOD

To the Editor:—*It is a common practice for the technical staff to draw venous blood between 8 and 9 a. m. for chemical examination, determination of erythrocyte sedimentation rate (Wintrobe), and, frequently, complete blood cell count. An oxalate mixture is used as the anticoagulant in a vacuum tube. The blood is examined within 30 minutes after arrival in the laboratory. No platelet counts are done in this fashion. Does this technique give clinically useful results in regard to the complete blood cell count?* *H. Seibel, M.D., Brooklyn, N. Y.*

Answer.—The technique described is probably adequate for the determination of red blood cell counts and hemoglobin level. The resultant white blood cell count is probably somewhat lower because of the rupture of white cells in the vacuum tube. The technique would not be satisfactory for good blood films in part because of destruction of white blood cells and in part because of the unsatisfactory stain after the use of anticoagulants. Because of the effect of the oxalate, the hematocrit reading would also probably be inaccurate. In comparing results, it must be remembered that blood obtained in this fashion is venous blood and the results are not entirely comparable with the capillary blood obtained by finger puncture. The results, however, would be comparable when obtained by the same technique consistently.

ARTIFICIAL SWEETENING AGENTS

To the Editor:—*It has recently been said that the prolonged use of no-calorie sweeteners was harmful. What harmful effects might result from such use in general?* *M.D., Tennessee.*

Answer.—The conclusion of a report published by the Food Protection Committee of the Food and Nutrition Board (National Research Council, August, 1955) can be taken as reflecting the current attitude concerning the use of artificial sweetening agents: "There is no evidence that use of the nonnutritive sweeteners, saccharin and cyclamate, for special dietary purposes is hazardous. In the case of cyclamate, unrestricted use in foods and beverages may result in the formation of soft stools, but probably without interference with other functions of the intestine and without hazard to health. No data have been presented as to the minimum laxative dose of cyclamate for children, but it is reasonable to assume that this dose is lower than for adults. The maximal amount of saccharin likely to be consumed is not hazardous. No adverse synergistic effect was observed in combinations of saccharin and cyclamate as tested. These materials should be subject to continuing observation for possible deleterious effects under prolonged and varying conditions of use and should be reappraised whenever indicated by advances in knowledge."

ANTICOAGULANT THERAPY

To the Editor:—*A 65-year-old man has moderate essential hypertension and generalized arteriosclerosis. He recently had a mild cerebrovascular accident, characterized by paresis of the right upper and lower extremities, and is gradually improving six weeks after the accident. Would it be advisable to institute anticoagulant therapy on a long-term basis for prophylaxis of further thrombotic episodes of the cerebral vessels? Also, would it be advisable to use rutin and one of the citrus flavinoid compounds?* *M.D., Ohio.*

Answer.—Anticoagulants should never be used in any form of therapy unless (1) the patient will consistently and scrupulously follow the doctor's directions and (2) accurate laboratory facilities are available to measure prothrombin time. There is no unequivocal evidence that treating elderly patients with generalized arteriosclerosis and hypertension will be of any value in preventing subsequent strokes, though there are enthusiastic supporters of this form of therapy. Direct treatment of the hypertension with methods aimed at lowering the blood cholesterol level and general hygienic care probably constitute the best available therapy at the present time. There is no evidence that flavinoids or rutin are of any value in the circumstances outlined or in other clinical conditions for which they have been recommended enthusiastically but not critically.

POLLEN FILTERS

To the Editor:—*Please give information and references on the most effective air-conditioning filter system for removal of pollen during hay-fever season, particularly the ragweed and grass pollens occurring in the Wisconsin area in June, July, August, and most of September.*

M.D., Wisconsin.

Answer.—There are numerous excellent filters on the market being used in air-conditioning equipment. It would be impossible to give an unbiased appraisal of any particular brand. Since ragweed pollen measures 15-20 μ in diameter, almost any good impingement filter would be effective to some degree. The Air Processing Committee (a subcommittee of the Committee on Air-borne Allergens) of the American Academy of Allergy has been studying this problem and testing filters and air-conditioning equipment for several years. In its most recent report (*J. Allergy* 28:455, 1957), a combination of an impingement type of filter in conjunction with an electrostatic precipitator type is recommended. Such devices have been described by

Novey and co-workers (*J. Allergy* 27:398, 1956) and Friedlaender and Friedlaender (*Ann. Allergy* 12:419, 1954).

USE OF OLD SURPLUS THIOPENTAL SODIUM

To the Editor:—*Does thiopental sodium deteriorate in the ampuls? A hospital recently acquired a supply of thiopental, a surplus item, which had originally been furnished to the U. S. Army in February, 1945. Is it safe to use it intravenously for anesthesia?*

Duncan C. McKeever, M.D., Houston, Texas

Answer.—This question is difficult to answer, since the factors concerned in the storage are unknown. However, tests on ampuls of this vintage only a year ago showed that the thiopental did not deteriorate to any great degree and that the toxicity did not increase with the passage of time when the ampuls were properly stored. Excessive heat and excessive light may accelerate deterioration, but more deleterious than this would be the minor breaks that occur in many types of ampuls. The skilled individual could make a solution of this particular vial, and, if it appeared to the naked eye to be normal, that is, if there was no clouding or precipitation, it would be considered safe to use. However, alterations in color and clarity would indicate that the ampul should be discarded.

PARALYSIS AGITANS

To the Editor:—*Is any form of paralysis agitans (Parkinson's disease) communicable?*

M.D., Pennsylvania.

Answer.—Paralysis agitans is not communicable. This clinical neurological syndrome may be the result of a wide variety of etiological agents. These agents include such infections as encephalitis and (rarely) syphilis. In most instances, paralysis agitans occurs long after initial infection, and transmission of the initial etiological agent is improbable at the time of the clinical manifestation of the disease syndrome.

VON GIERKE'S DISEASE

To the Editor:—*Please supply information on the use of pituitary extract to increase the growth of a 13-year-old boy with diagnosed Von Gierke's disease. His present height is 47 in. (88.9 cm.) and his weight 47 lb. (21.3 kg.). What other regimen of treatment might be of value?*

Henry G. Kurz, M.D., La Habra, Calif.

Answer.—The literature on this condition is not voluminous. The most illuminating article that has come to this consultant's attention is "Effect of the Menarche on Hepatomegaly in Pubescent Girl with Syndrome Resembling Glycogen Disease" (Esselborn and others, *J. Clin. Endocrinol.* 10:339, 1950). On the basis of this and general considerations, this boy could be given gonadotropins, either equine or chorionic or these in alternation, thyroid in tolerance doses, and methyltestosterone, 10 mg. sublingually twice daily; also, cortisone might be tried. None of these, nor all of them together, offer any great promise. Pituitary growth hormone should be useful when effective preparations are available.

PROGRESSIVE PIGMENTARY DERMATOSIS

To the Editor:—*A query on progressive pigmentary dermatosis appeared in* The Journal, *Aug. 23, 1958, page 2161. Current textbooks, such as those by Sutton, Ormsby, and Montgomery, do not touch on the etiology and pathogenesis of this condition, and only Sutton suggested the use of x-ray treatment. Progressive pigmentary dermatosis (Schamberg's disease) is due to a clear-cut deficiency of vitamin C, and, as such, it is an etiological equivalent of scurvy. The treatment with vitamin C, 150 mg. given three times a day until the lesions disappear, is efficient in every instance. In my experience, the patients with this disease had not had citrus fruits in their diet for years. This deficiency in the patient's diet should be, of course, eliminated.*

Tibor Benedek, M.D.
25 E. Washington St.
Chicago 2.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*The group of dermatoses to which progressive pigmentary dermatosis belongs, and which includes purpura annularis telangiectodes (Majocchi's disease), Gougerot's syndrome, and Blum's disease, is noted, among other changes, for purpura. The purpuric lesions are small and often punctate and yet unlike the early follicular forms seen on the lower extremities in scurvy. Overt manifestations of scurvy in the above group, such as swollen and bleeding gums, are lacking. Nevertheless, progressive pigmentary dermatosis and related entities (some believe they are clinical variants of one disorder) may have a direct or indirect basis in a relative vitamin C deficiency. This should be easily verified in the clinical laboratory. This consultant is not aware of any reports on blood vitamin C levels in progressive pigmentary dermatosis. If the simple measure of vitamin C administration will suffice to clear this group of purpuric dermatoses, it is a welcome therapeutic suggestion and will be received gratefully.*

WASHINGTON NEWS

Doctor Cooperation in International Health Urged . .
AFL-CIO Gives High Priority to Welfare Bills . .
PHS Cites Disease Factor in Air Pollution . .
New Physician in Congress . .
Doctors on White House Group for Youth . .
Library of Medicine Gets New Regents . .

FIRST REPORT ON INTERNATIONAL HEALTH STUDY

A senate Government Operations subcommittee has made its first report on a broadscale study of "any and all matters pertaining to international health, research, rehabilitation, and assistance programs"—with particular reference to the U. S. contributions. Chairman of the group is Senator Hubert Humphrey (D., Minn.). The study was authorized by the last Congress.

The initial report which deals with medical research observes that "it is the hope of men of good will everywhere that more and more of the energies of all nations be channeled to the constructive purpose of furthering the well being of man." To this end, teamwork is essential from a number of groups. The report lists in this connection "the great system of private medicine and of all the members of the professions allied to medicine" and the private pharmaceutical and chemical industries "whose research contributions grow with each passing day."

It also called for teamwork between American foundations, voluntary health organizations, universities, and hospitals, as well as "between the governments of the nations of the world themselves."

"Today," the report added, "the complexity and volume of medical research render especially important the promptest possible exchange of scientific information and strengthened cooperation. In this way, precious time and effort may be saved and used to best advantage."

PHS CITES POLLUTED AIR AS DISEASE FACTOR

Public Health Service says it appears likely that the medical effects of air pollution are not confined to the respiratory and circulatory systems. In a pamphlet issued in advance of its National Air Pollution Conference, PHS says the theory is still unproved but supported by accumulating evidence that air pollution contributes significantly to mortality rates of many of the urban diseases, such as arteriosclerotic and heart conditions and cancer of the lungs, trachae, stomach, and esophagus.

Epidemiological and statistical studies show parallels between air pollution and mortality rates from cancer of the stomach and esophagus, similar to those from lung cancer, PHS said. Mortality rates for lung cancer among urban dwellers are significantly higher than among strictly comparable rural groups, smoking habits notwithstanding. Statistical studies now under way show possible parallels between lung cancer rates and air pollution indices, according to PHS.

Comments a second report on the economic effects of air pollution: "It is impossible to add up the cost of pollution in one column and the cost of an ideal pollution prevention program in another and prove the economy of maintaining a high quality of air. Nevertheless, it is quite apparent that the estimated third of a billion dollars now spent for prevention is out of line with the estimated 4 billion dollars spent for neglect. More money put into the asset side would remove several times as many dollars from the debit side."

Over 70 air pollution specialists, civic leaders, and representatives of industrial and governmental agencies dealing with air pollution problems are on the program on the National Conference. The conference will review recent knowledge about air pollution and recommend future plans for dealing with the problem.

Surgeon General Leroy Burney and HEW Secretary Arthur Flemming are the principal speakers. Others include Dr. Edwin D. Harrison, president, Georgia Institute of Technology; Chauncey D. Leake, American Association for the Advancement of Science, and Martin Agronsky, news commentator, who will summarize the conference discussions.

Public officials on the program are Senator Kuchel (R., Calif.), who developed the federal legislation on air pollution control; Mayor R. Tucker of St. Louis; Dr. Herman E. Hilleboe, New York state commissioner of health, and Dr. Malcolm H. Merrill, director of the California department of public health.

Speakers on the industrial role in air pollution control are Gen. John E. Hull, president of the Manufacturing Chemists Association; Max D. Howell, executive vice-president of the American Iron and Steel Institute; Harry A. Williams, managing director of the Automobile Manufacturers Associa-

(Continued on next page)

tion; and Dr. Jerry McAfee, chairman of the smok and fumes technical advisory committee of the American Petroleum Institute.

LABOR SEES ELECTION MANDATE FOR MORE WELFARE PROGRAMS

Hospitalization and surgical services for the social security beneficiaries are now no. 3 on the legislative agenda of the AFL-CIO, which says the recent elections calls for "bold forward steps for the welfare of all America." President George Meany has this to say in his 12-point legislative program:

"Adopt the Forand bill to provide hospital and surgical care for the recipients of old age and survivors insurance benefits. It is still either impossible or too costly for our senior citizens to obtain such insurance through non-profit or commercial channels."

Mr. Meany told a press conference: "By an overwhelming vote, they elected to Congress new Senators and Representatives who want to forge ahead and properly utilize our nation's human and natural resources to build a better world for all. By the same token, they retired many members of Congress who have followed a standstill policy."

He said the union was hopeful that "now that the people of America have spoken that prompt and vigorous action will result. This is not the time to raise false issues. This is the time to give the American people the program for which they have voted."

The two issues ahead of the hospitalization proposal are aid to depressed areas and adequate federal aid to general education.

NEW PHYSICIAN IN CONGRESS–TWO OTHERS LOSE

A physician new to politics has been elected to the House of Representatives, while a veteran physician member of the House will be assuming the chairmanship of the Foreign Affairs Committee. Two other doctors long in Congress lost out on reelection.

Dr. Dale Alford, a board ophthalmologist from Little Rock, Ark., is the new Democratic Representative from the fifth district of Arkansas. He is the son of a public school administrator, was educated in Arkansas schools, and received his medical degree from the University of Arkansas. Dr. Alford served in the Army Medical Corps in World War II and has been in active practice in Little Rock since 1948. He is 42.

Dr. Thomas Morgan (D., Pa.), who has completed 14 years in the House, is scheduled to become chairman of the Foreign Affairs Committee. According to committee sources, he would be the first physician chairman of that important committee in the 136 years of its existence.

Dr. Will Neal (R., W. Va.), who has been active on the health subcommittee of the House Interstate Committee, and Dr. A. L. Miller (R., Neb.), long on the Interior and Insular Affairs Committee, failed to be reelected. Back for another two years as a result of the voting are Drs. Walter Judd (R., Minn.) and Ivor Fenton (R., Pa.).

TWO DOCTORS ON WHITE HOUSE YOUTH CONFERENCE

Two physicians have been named among 12 leading citizens by the President to serve on the national committee for the White House Conference on Children and Youth. It will be held in March, 1960. They have the position of vice-chairmen.

One is Dr. Edward D. Greenwood, coordinator of training in child psychiatry, Menninger Foundation, Topeka, Kan. The other is Dr. Daryl P. Harvey, staff physician on the Howard Clinic, Glasgow, Ky.

Other vice chairmen are Hurst Anderson, Ph.D., president of American University; Mrs. James Blue, National Association of Governing Boards of State Universities and Allied Institutions; Robert E. Bondy, director, National Social Welfare Assembly; Erwin D. Canham, editor, Christian Science Monitor; Donald K. David, Ford Foundation; Msgr. Raymond J. Gallagher, Catholic Charities of Cleveland; Mrs. Frank Gannett, of Gannett Newspaperboy Scholarship Inc.; Donald S. Howard, chairman of the National Council of State Committees for Children and Youth; Rabbi Marc Tanenbaum, executive director of the Synagogue Council of America, and the Rev. William J. Villaume of the National Council of Churches of Christ.

President Eisenhower will serve as honorary chairman and Secretary Arthur Flemming of HEW as honorary vice-chairman. Mrs. Rollin Brown, past president of the National Congress of Parents and Teachers, is the conference chairman, and Mrs. Katherine B. Oettinger, chief of the U. S. Children's Bureau, is secretary.

LIBRARY OF MEDICINE REGENTS

Three regents who will serve four years have been named to the National Library of Medicine by President Eisenhower. At its first meeting of the fall, the board of regents elected as their chairman Dr. Champ Lyons, professor of surgery and chairman of the department of surgery at the Medical College of Alabama. Dr. Lyons has been on the board since 1956.

Two of the new regents are physicians. Dr. William B. Bean is professor of medicine and head of the department of internal medicine, State University of Iowa College of Medicine. Dr. William Stadel, a former hospital administrator, is director of the San Diego (Calif.) Department of Medical Institutions. The third regent is Mrs. Eugenie Mary Davie of New York, chairman of the women's auxiliary of the New York Republican County Committee since 1946.

Dr. Lyons succeeds as chairman Dr. I. S. Ravdin of Philadelphia, whose term has expired.

ROLE OF URETER IN PATHOGENESIS OF ASCENDING PYELONEPHRITIS

Herbert S. Talbot, M.D., West Roxbury, Mass.

It is suggested that the ureter has a dual role in the pathogenesis of most cases of ascending pyelonephritis. Anatomically the ureter provides a direct route of invasion from bladder to kidney because the subepithelial tissues of the bladder, ureter, and renal pelvis are continuous with the interstitial tissue of the kidney. Physiologically the diseased ureter increases the susceptibility of the kidney to infection because ureteral dysfunction generally involves both obstruction and vesicoureteral reflux. The ureter is not an inert tube but an active muscular structure, and recognition of this fact leads to a dynamic, rather than a static, concept of ascending pyelonephritis.

PYELONEPHRITIS is a collective term applied to a number of different types of renal infection with varying manifestations.[1] It cannot be expected, therefore, that a single pathogenic process might be invoked to account for the evolution of the disease in every instance. Careful study of a group of similar cases, however, has suggested a sequence of events applicable to that group, from which conclusions may be drawn that perhaps have broader implications. This has included not only the correlation of clinical and pathological findings but also consideration of the pathological physiology of the urinary tract during the development and course of the disease.

For the purpose of this discussion, the term "ascending pyelonephritis" will be applied to those cases in which renal involvement is accompanied or preceded by infection in the lower urinary tract, from which it may reasonably be supposed to have been derived. Bacterial evidence of this relationship does not in itself indicate the manner in which the process has spread. It will be suggested that the ureter has an important role in this pathogenesis—a dual role—in that the wall of the ureter first provides a pathway for the actual ascent of the invading organism and, second, as a result of the changes which it undergoes during this process, exhibits a dysfunction which results in stasis, contributing further to the development of infection in the kidney. This concept, although independently reached, is not original,[2] but has not previously been emphasized.

There are four routes by which infection, originating in the bladder, might reach the kidney: (1) hematogenous, (2) lymphogenous, (3) through the lumen of the ureter, and (4) through the ureteral wall. Hematogenous pyelonephritis may occur, and be the only apparent secondary focus to de-

velop, from a known primary site of infection. When this site is remote from the kidney, the blood stream is the most likely channel for the transmission of pathogenic organisms; gram-positive cocci are the usual invaders in such cases. With the original infection in the bladder, a question arises as to whether this roundabout course is more probable than direct invasion through or along the urinary tract itself. The most frequent pathogens are gram-negative bacilli, and they are rarely cultivated from the peripheral blood. Material for histological examination is seldom obtained at the early stage of disease when the route of invasion might be suggested by such evidence as perivascular infiltration, in the case of hematogenous infection. Biopsy findings, however, suggest that in the acute stage the primary reaction is tubular.[3] The dissemination and evolution of the intrarenal lesions is such as to obscure early changes and make it difficult if not impossible to differentiate one type of pathogenesis from the other. The fact that healed experimental pyelonephritis of hematogenous origin histologically resembles certain specimens obtained from human cases does not, therefore, imply that the human cases were also hematogenous.

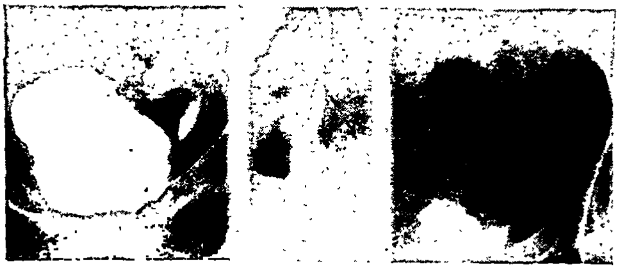

Fig. 1.—Vesicoureteral reflux with compensated ureteral function. With bladder full, there is reflux into left ureter; as bladder empties, ureter empties as well..

Oberling[4] has pointed out that the lesions of pyelonephritis are basically interstitial, whether ascending or hematogenous in origin, and that they are to be distinguished mainly by their distribution. In the ascending form, the infiltration develops in tracts running over considerable areas from the pelvis toward the capsule. They may be diffuse and uniform, but, more often, the lesions leave between them areas of undamaged parenchyma. In the hematogenous form, on the other hand, the inflammatory foci are more prone to form a subcapsular band with perpendicular tracts developing especially around the interlobular vessels, in accordance with the concept of a perivascular stroma particularly prompt to react to any irritative influence. This may occur as well with ascending involvement *when it has gone on long enough* to involve the same areas, thus obliterating any differences between the ascending and hematogenous types.

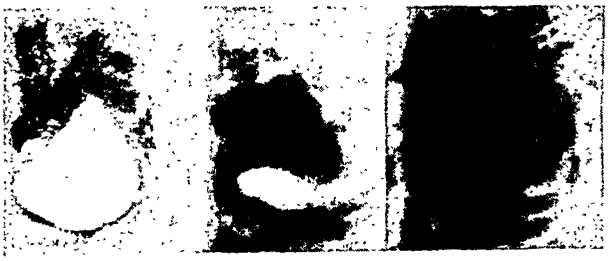

Fig. 2.—Vesicoureteral reflux with ureteral decompensation. Ureter is unable to empty with bladder.

Ureteral Obstruction

Mallory, Crane, and Edwards[5] showed that the production of experimental hematogenous pyelonephritis in previously healthy kidneys depends on the presence of partial ureteral obstruction. The clinical association of intermittent or chronic pyelonephritis with obstructive lesions of the urinary tract, and particularly of the ureter, has often been noted.[6] However the organisms reach the kidney, therefore, their capacity to do damage is considerably enhanced by, if it does not depend on, some degree of stasis of the urinary column. Certain bacteria, particularly staphylococci, injected intravenously may infect normal kidneys. De Navasquez[7] accomplished this with a coagulase-positive Staphylococcus pyogenes var. aureus and attributed the establishment of infection to coagulase production, which initially causes agglutination in the unusually long renal capillaries devoid of phagocytes; the sub-

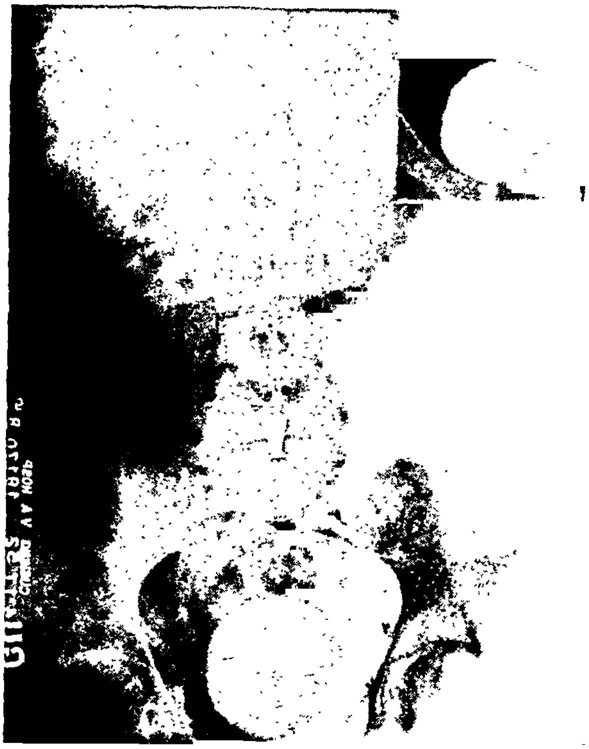

Fig. 3 (case 1).—Reflux into right ureter. Inset shows spot film demonstrating transitory reflux up left ureter.

sequent diffusion of coagulase into the surrounding parenchyma leads to coagulation necrosis, followed by suppuration. These factors do not operate in the case of the gram-negative bacillary organisms normally associated with urinary tract infections.

Asher and Sokol[8] demonstrated that blood-borne foreign particles have but a slight tendency to localize in the kidney, which, when normal, does not excrete living bacteria circulating in the blood. They observed, however, that acute experimental hydronephrosis increased the tendency for blood-borne particulate matter to localize, apparently as a result of stasis. Lucas[9] suggested that an increase in intrapelvic pressure has the effect of slowing down the circulation of blood through the kidney, producing some renal damage and favoring the trapping of organisms in narrow capillaries. In a later series of experiments, De Navasquez[10] injected coliform bacteria intravenously into rabbits which had recovered from the pyelonephritis previously induced by coagulase-positive Staph. pyogenes var. aureus, but with kidneys scarred as a result thereof. All developed a fatal pyelonephritis, while normal control animals developed no kidney lesions. He attributed this to the obstruction of tubular drainage by the scars, with resulting "intrarenal hydronephrosis," and increased local tissue pressure.

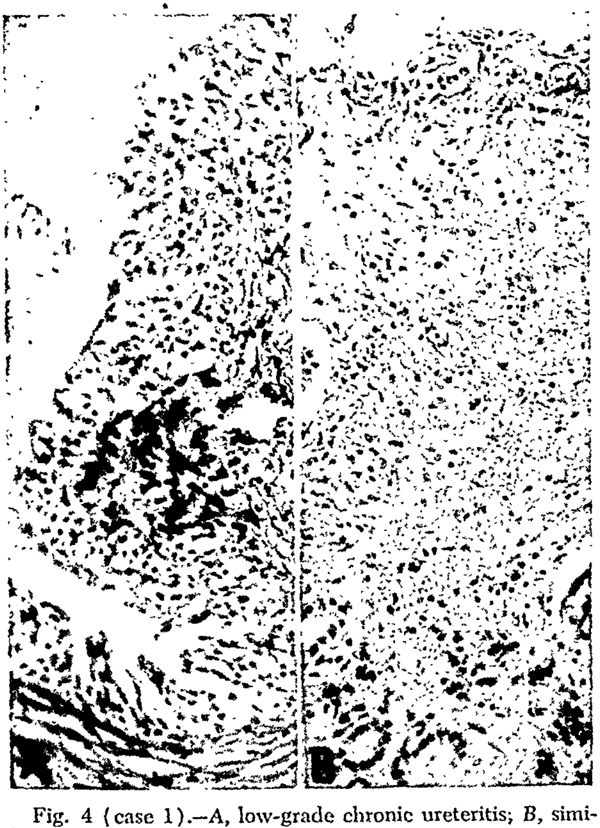

Fig. 4 (case 1).—*A*, low-grade chronic ureteritis; *B*, similar changes in kidney.

Beeson, Rocha, and Guse[11] found that small lesions in the renal medulla, produced by an electric cautery, render an entire segment of kidney tributary to the tubules passing through that portion of the medulla susceptible to coliform infection. This result was obtained whether the infecting bacteria were introduced via the blood stream or the urinary bladder. They agreed with the explanation offered by De Navasquez insofar as it postulated obstruction of tubular drainage, but could not accept his further suggestion that another element is local slowing of the circulation, since this did not appear to be the case in the pathogenesis of pyelonephritis in animals with ureteral ligation. If Lucas' contention that an increased intrarenal pressure produces slowing of the blood flow through the kidney is correct, however, such a factor might be significant. Whatever the precise mechanisms, it is apparent that trauma will favor the probability of invasion by any route. Braude, Shapiro, and Siemienski[12] accomplished this by massage of the exposed kidney in rabbits subjected to the intravenous inoculation of gram-negative bacilli. It has also been suggested that not only acquired pathological changes but congenital dysplasias as well may predispose the kidney toward infection.

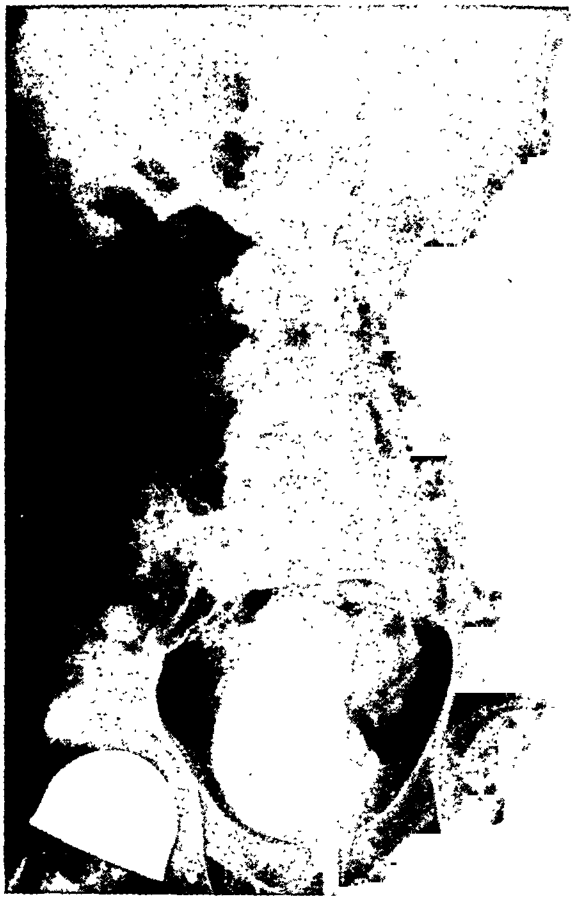

Fig. 5 (case 2).—Right reflux with hydronephrosis.

When there is a bacteremia during the course of a lower urinary tract infection, hematogenous infection may occur provided that at least one of two prerequisites has been met, a previously damaged kidney or obstruction of the ureter. In their absence, and lacking the further confirmation of a positive blood culture of gram-negative bacilli, such a pathogenesis is unlikely.

Lymphogenous ascent of infection from the bladder to the kidney has been suggested, and the possibility is supported by the frequent involvement of periureteral lymphatic channels. But Winsbury-White's demonstration [13] of the spread of india ink into these lymphatics from the bladder is not conclusive evidence that living organisms propagate along the same route. The major lymphatic drainage of the urinary bladder is into the pelvic and iliac chains. The periureteral lymphatics drain the ureter and renal pelvis, and a lymphangitis in this area may, therefore, be presumed to be secondary rather than to represent a primary invasion pathway.

Ascent of infection through the column of fluid within the ureteral lumen is at least theoretically possible and has been ingeniously demonstrated in an artificial urinary tract. In the experiments of Weyrauch and Bassett,[14] motile organisms ascended only in a stagnant column, however, or against a flow of less than 25 cc. per hour. Once again, therefore, an element of obstruction must be postulated. In the presence of such obstruction, it is difficult to conceive of pathogenic bacteria moving and multiplying within the lumen without attacking the wall of the ureter. But this is even more susceptible to invasion, by direct contiguity, from an infected bladder. The lamina propria or subepithelial layer is a continuous structure from the bladder to the renal pelvis where it merges with the interstitial tissue of the kidney. Rényi-Vámos [15] found this to be a pathway for the spread of infection in both human and experimental ascending pyelonephritis, an observation confirmed by others, usually with a reference to associated ureteral obstruction. Allen [16] refers to the ureter as being "obviously continuously infected from the site of obstruction upward to the kidney." The significance of such a pathway becomes apparent when its effect on ureteral function is appreciated.

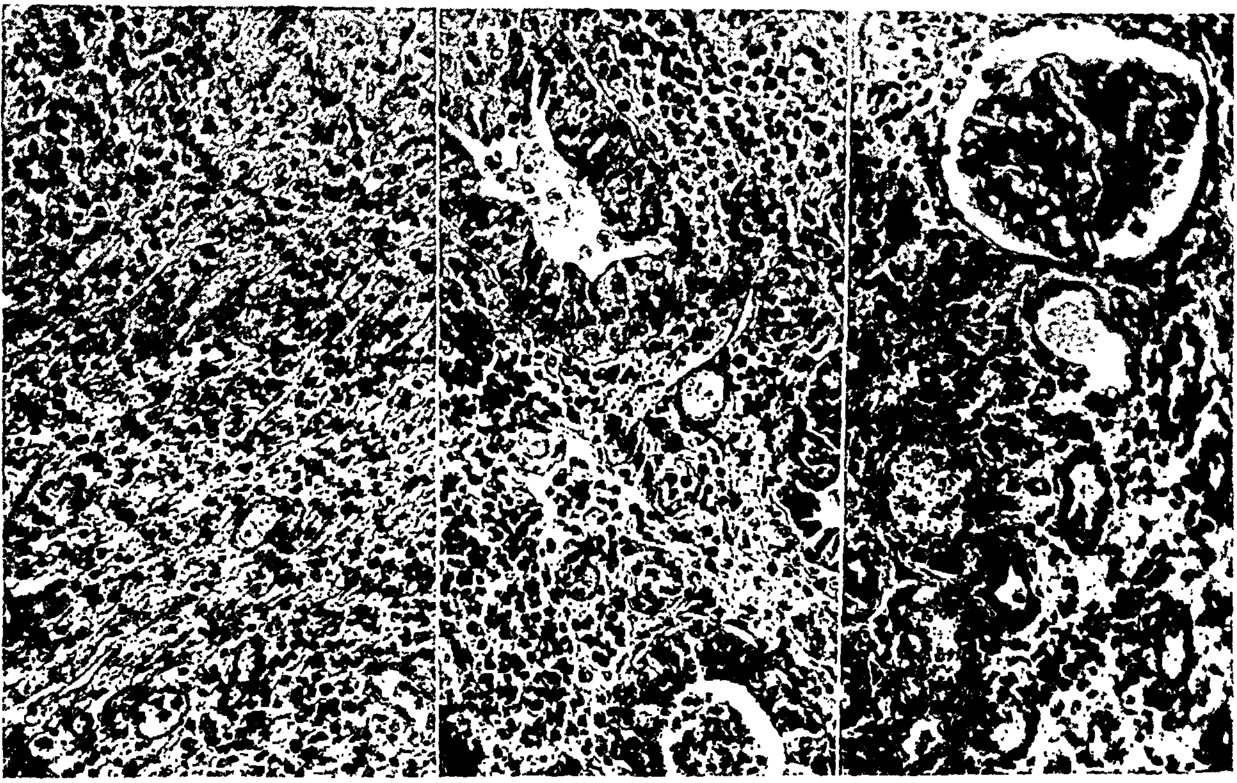

Fig. 6 (case 2).—*A*, midureter section showing ureteritis; *B*, similar findings in calyces of kidney; and *C*, cortex of kidney.

Role of Ureter in Pyelonephritis

Investigations into the normal and pathological physiology of the ureter, demonstrating its importance in the dynamics of urinary flow, lead to the concept that its disease and consequent dysfunction may contribute to the development of pathological changes in the kidney.[2] The significance of this in ascending infection was suggested by the study of pyelonephritis associated with vesicoureteral reflux in patients with spinal cord injury. In the review of a series of such cases, it was noted that dilatation of the ureter began at its lower end and advanced upward. In fact, such evidence of progressive disease is of greater prognostic importance than the demonstration of reflux itself, which is often capricious in its appearance and disappearance. It has been axiomatic to interpret ureteral dilatation as a consequence of obstruction distal to the dilated segment, but this raised two interesting considerations. First, mechanical obstruction was not demonstrated in any of the cases from which this study developed. It was evident that the obstructive factor, if any, must be functional rather than structural. Second, it was difficult to understand why an organ like the ureter, limited in length and draining a hydraulic system closed at its proximal end, should react to obstruction by dilatation involving only a short segment. Dilatation of the whole system proximal to the obstructive lesion would have seemed likelier; this is observed when a stone becomes impacted in a previously healthy ureter, as well as in other types of mechanical obstruction, when there is no infection.

It thus becomes necessary to consider other possible causes for dilatation. The most obvious would be an alteration in the wall of the ureter, of such character as to interfere with normal contraction of its muscle. It would also have to be of such a nature as to account for the fact that in some instances the lower ureteral dilatation spread upward, finally to involve the pelvis of the kidney; in others, it remained unchanged for long intervals, and in still others regressed. Inflammatory disease would meet all these conditions, waxing or waning or remaining unchanged, and, in some instances, finally reaching an irreversible state of fibrosis. But this is precisely the type of lesion to which the ureter, beginning with its lower segment, is most vulnerable by direct contiguity to an infected bladder. As already noted, a continuous pathway of areolar tissue is available throughout its length, in which invading organisms may advance from the bladder to the interstitial tissues of the kidney. This inflammatory involvement of the wall of the ureter, and ultimately of the renal pelvis and calyces, interferes with normal peristaltic activity and results in stasis. When this has occurred, infection may spread through the lumen as well as the wall.

The concept of the ureter as a relatively inactive conduit through which fluid flows mainly by gravity must be discarded. It is, on the contrary, an organ of great dynamic capacity, with two functions. The first is the propulsion of urine from the kidney to the bladder. The second is generally stated to be the prevention of retrograde flow from the bladder back to the kidney. More is involved in this, however, than the prevention of reflux. Simple regurgitation from the bladder into the ureter would be harmless enough were there no stasis or infection. There has been considerable discussion as to whether reflux ever ocurs in the absence of pathological changes. If it does, it is probably transitory and of no great physiological significance. But reflux does become important when it is an evidence of ureteral dysfunction leading to ureteral and pelvic stasis and when, as was always the case in this study, it occurs in the presence of infection of the lower urinary tract. This infection, advancing from the bladder into the wall of the ureter, results, first, in dysfunction of the lower segment.

Without entering into a discussion of ureteral physiology, it is sufficient to state that there is evidence that the activity of the lower segment constitutes, in fact, a dynamic ureterovesical valve. Anatomically, its wall is the thickest of any portion of the ureter, and its outer muscular layer merges indistinguishably with the musculature of the bladder. The lower third of the ureter, moreover, is supplied with parasympathetic ganglions identical to those in the adjacent portions of the bladder wall; the latter were found diminished in number in a case of congenital megaloureter. Thus, there is strong anatomic presumption of an intimate functional relationship between the bladder and the lower ureteral segment.

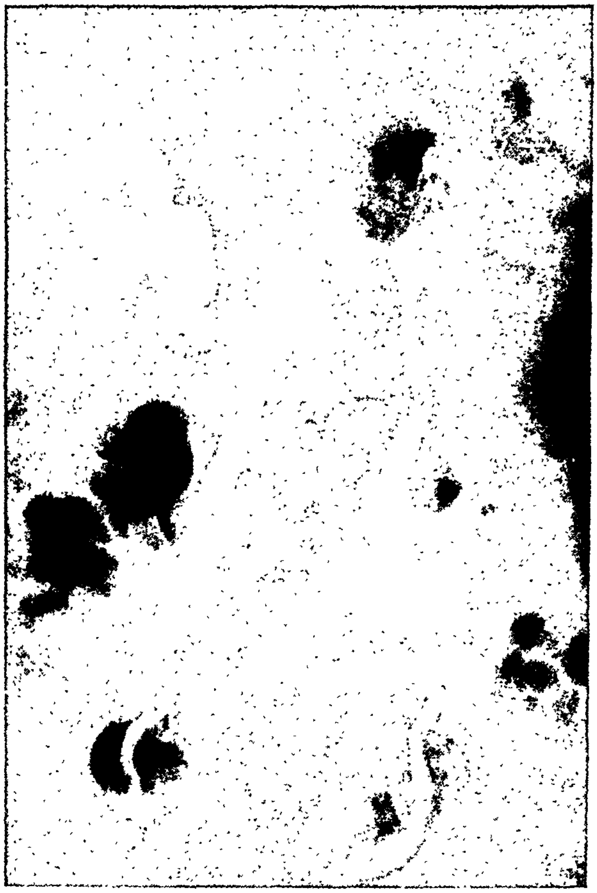

Fig. 7 (case 3).—Hydronephrosis from functional obstruction.

Gould, Hsieh, and Tinckler[17] have suggested that the lower end of the ureter has a task somewhat different from that of the upper and that the integration of tonic and peristaltic activity is such as normally to protect the nephron from the high basic pressures which arise in the lower segment when it is operating to handle large quantities of urine or against elevated intravesical pressures.

Fluoroscopic studies, including recent cinefluorographic investigations, have demonstrated that the lower ureter does, in fact, contract during or immediately after an emptying contraction of the bladder. Again, fluoroscopically, it has been possible to demonstrate that in some patients with vesicoureteral reflux the mechanism remains sufficiently well compensated to operate in approximately normal fashion, and in such instances the kidney may remain undamaged for months or even years (fig. 1). When the process becomes so severe, however, as to be incompatible with normal function, and especially when it advances upward in the ureter and to the renal pelvis, such compensation is impossible and hydronephrosis develops (fig. 2). Even before anatomic hydronephrosis can be demonstrated, however, pressure changes, damaging to renal function and conducive to infection, may already be present. Reverse peristalsis, long since observed in the presence of mechanical obstruction, has more recently been seen to occur also in this functional type.

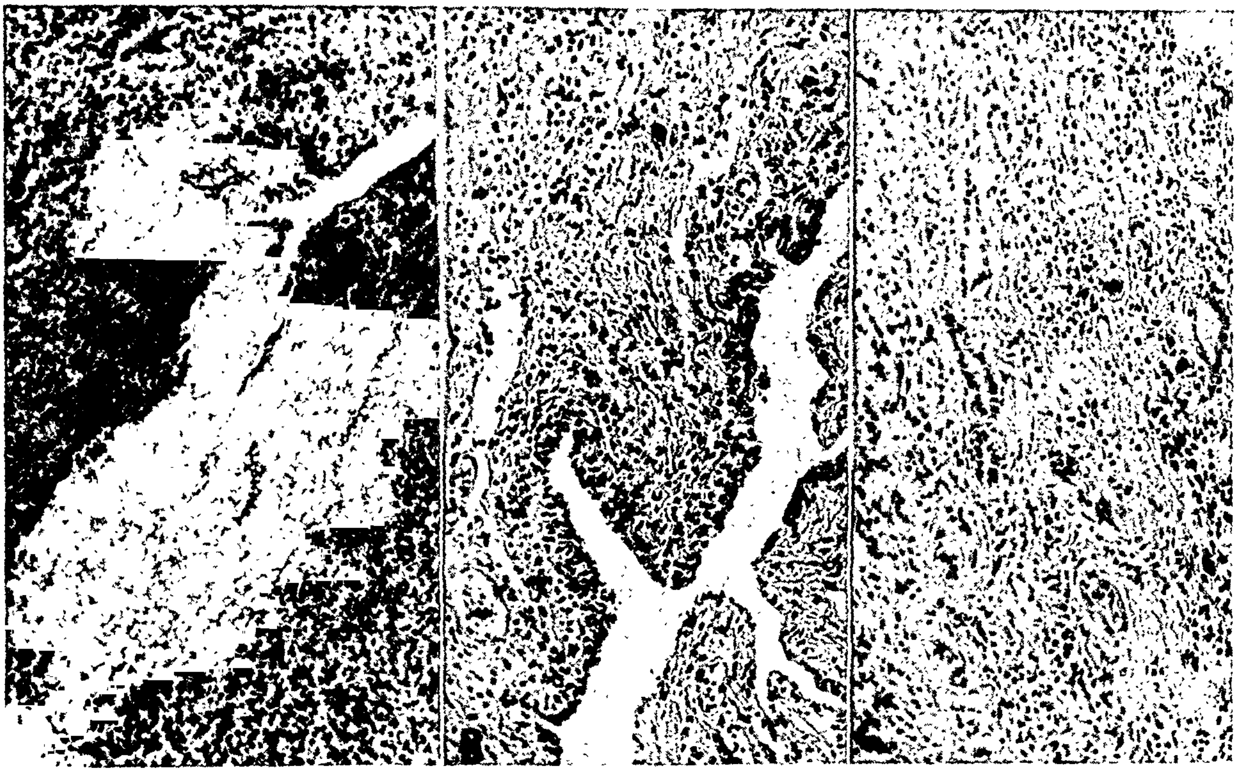

Fig. 8 (case 3).—*A*, acute uretitis in lower ureter; *B*, chronic ureteritis in upper ureter; and *C*, chronic pyelonephritis in kidney.

Thus, by means of serial x-ray studies carried on over a period of months or years, in patients known at the beginning to have infections in the lower urinary tract, and particularly by utilizing those x-ray techniques which make dynamic studies of function possible, changes in the structure and activity of the ureter can be followed and are a strong determinant in favor of the development of pyelonephritis. The same changes can also be interpreted as evidence of infection of the ureteral wall itself. In the continued absence of mechanical obstruction, only an inflammatory process could account for the fact that these abnormalities sometimes advance, sometimes regress, and sometimes remain unchanged for considerable intervals.

Autopsy Findings

In a review of the protocols of a series of autopsies done during a period prior to the institution of this study, 11 cases of ascending pyelonephritis were found. In none of these were there urinary calculi or any other form of mechanical ureteral obstruction. In all 11, the ureter was described as grossly abnormal, usually dilated or thickened, or both. Microscopic studies of the ureter were made in seven cases, in all of which inflammatory changes were seen, confirming the probability that the ureteral wall had served as a pathway of invasion. The next step was to demonstrate this in patients in whom the x-ray findings noted above had been observed.

Case 1 was that of a quadriplegic patient with mild chronic pyelonephritis who died of unrelated causes. The ureters had shown slight transitory dilatation in the lower thirds and reflux had been seen occasionally, although not on every examination. At the time of death there was no clinically active urinary tract infection. Sections of the ureteral wall showed slight infiltration with lymphocytes and plasma cells, with fibrosis and edema in the subepithelial layer. Essentially the same findings were noted in the kidney pelvis. The fact that even a quiescent process of low grade could be demonstrated as coexisting in the ureter and the kidney seemed a suggestive clue to the pathogenesis (fig. 3 and 4).

In case 2, the involvement of one kidney was so severe as to require nephrectomy. The patient was a paraplegic who exhibited unilateral vesicoureteral reflux with apparently complete ureteral decompensation. Sections of the ureter, taken where it was divided at about its midpoint, showed a process strikingly similar to that involving the kidney (fig. 5 and 6).

Urinary tract infection in patients with spinal cord injury has no special characteristics; similar findings have been encountered when the primary disorder in the bladder was other than neurogenic. This is shown in case 3, a man of about 60 who died of uremia resulting from long-standing neglected prostatic obstruction. The kidneys showed chronic pyelonephritis. Acute cystitis was present, and it was postulated, therefore, that the lower ureter should show a fairly severe acute reaction, the upper a chronic and less intense process. This is exactly what was found. Such changes, of course, might well be sufficient to impair peristaltic function, temporarily at least, and to alter significantly the tone of the ureteral wall, leading first to moderate dilatation and later, if the process became irreversible, to functional obstruction and further dilatation, such as marked the end stage in this patient (fig. 7 and 8).

Case 4 was that of a man with carcinoma of the prostate and disseminated metastases. The pathological changes were easily traced from the bladder through several sections of the ureter to the kidney (fig. 9).

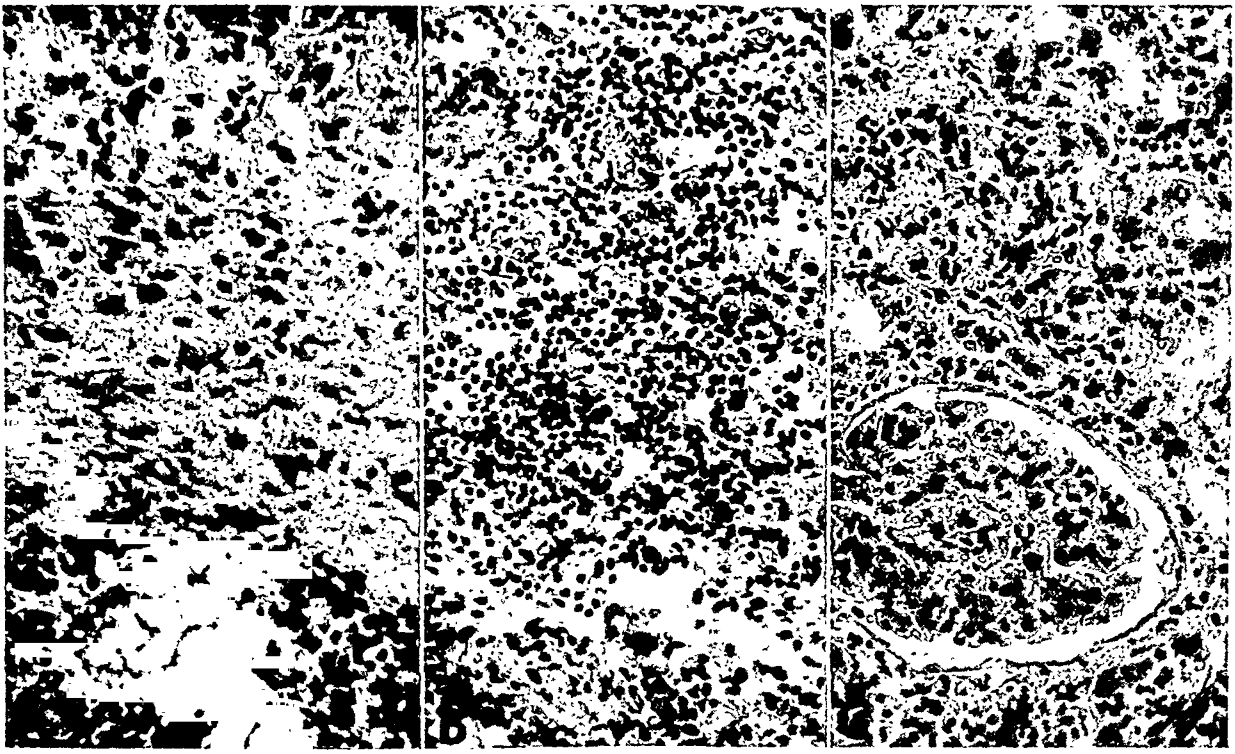

Fig. 9 (case 4).—Pathological changes in carcinoma of prostate: *A*, bladder; *B*, ureter; *C*, kidney.

Since the ureteritis may be mild, or, if severe, may have healed, it is often difficult to establish its presence in specimens obtained at autopsy months or years after the event. This is particularly the case when the function has remained compensated so that there is neither dilatation nor hypertrophy. In such an instance, however, the telltale evidence of fibrosis, demonstrated by differential staining, will suggest past events. Case 5 was that of a man of 62 who died of a massive cerebral hemorrhage. Although cystitis had long been present, the kidney escaped significant damage. The ureter, grossly normal, showed considerable fibrosis in its lower segment and less in its upper, suggesting that it had contained the infection and maintained adequate function (fig. 10).

Prophylaxis and Therapy

This concept of the pathogenesis of ascending pyelonephritis, entailing the appreciation of a dual hazard to the kidney, suggests a dual approach in prophylaxis and therapy. The immediate problem is the elimination of infection, and the bladder, being the primary site, may be considered first. When there is obstruction it must be corrected. Pending this, drainage must be maintained. Whatever hesitancy there may be about undertaking the use of an indwelling catheter in an uninfected bladder, there can be no gainsaying its importance when infection is already present, as it may be even in patients who have not previously been subjected to instrumentation or catheterization. This applies particularly to those who carry residual urine. The danger of ureteral involvement is not eliminated by bladder drainage, but its likelihood is much diminished, especially if the drainage is part of a program aimed at restoring the bladder to normal function. When the obstruction is mechanical, surgical intervention leading to the elimination of residual urine will usually give a satisfactory result.

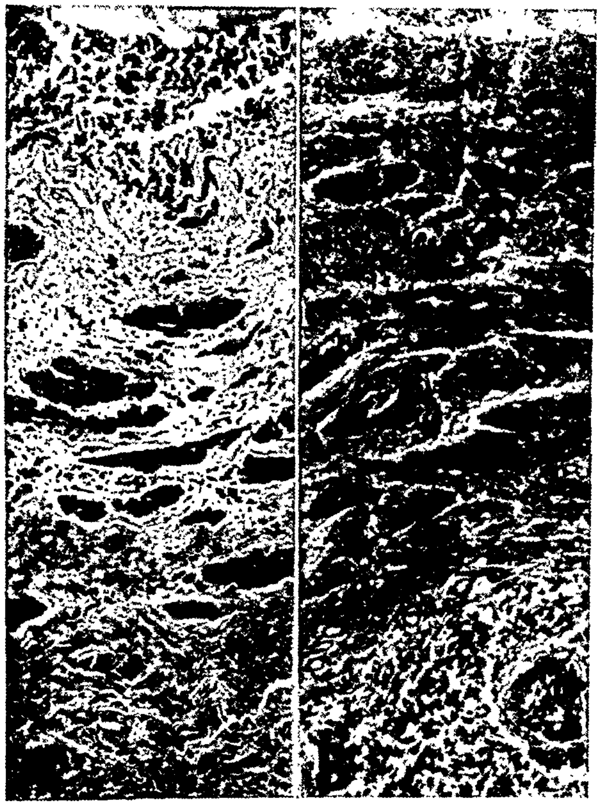

Fig. 10 (case 5).—*A*, lower ureter showing fibrosis; *B*, upper ureter, fibrosis of lesser extent.

Antibiotics or chemotherapeutic agents can be useful adjuvants during the course of treatment, but it is notorious that these alone have been disappointing in the chronic and recurring infections usually associated with obstructive uropathy. When the bladder's inability to empty is due to neurogenic dysfunction, the problem is more complex. Treatment usually involves continuous catheter drainage, sufficiently prolonged to cause almost certain urinary infection. This is a calculated risk, which must be faced. In spite of recent alarms to the contrary, it is a fact that continuous catheterization can be done for long periods of time without apparent damage to the kidneys. Even those who have emphasized the danger of the indwelling catheter recognize that it is sometimes inevitable. Rigid adherence to meticulous techniques and the retraining of the bladder on physiological principles which will shorten the period of artificial drainage further diminish the hazards and make the risk acceptable. If a satisfactory pattern of bladder function can be established and the involvement of the ureter avoided, the major danger to the kidney will have been forestalled.

When pyelonephritis is already present, appropriate constitutional measures and use of antibiotics and chemotherapeutic agents are again indicated for the treatment of the infection, but here the dysfunction of the ureter may call for additional measures to insure adequate drainage of the renal pelvis and protect the parenchyma from the deleterious effects of stasis. Again it must be recalled that the absence of any demonstrable mechanical obstruction means little or nothing. This emerged from empirical knowledge spread over a number of years before the concepts described in this paper had been developed. More frequently in those years than is now happily the case, paraplegic patients with neurogenic vesical dysfunction and urinary infection were prone to develop exacerbations of what was considered to be acute or subacute pyelonephritis, characterized by chills, fever, and leukocytosis. The problem of diagnosis was complicated by the fact that they did not exhibit the customary physical signs and that their urine was infected even when they were well.

The technique of quantitative cultures, since advocated by Kass and Finland[18] and by Beeson,[1] had not been used. X-ray evidence of ureteral dysfunction was often seen, but, on the other hand, it was sometimes found in those who never had these exacerbations. The therapeutic test ultimately clarified the diagnosis. Some patients improved on the administration of large quantities of intravenously administered fluids with various sulfonamide drugs. It became the policy to treat those who did not show improvement after 48 hours by lavage of the kidney pelves, followed by ureteral catheter drainage for 24 to 72 hours. This procedure was almost invariably dramatically successful. Mechanical obstructions were not found, accumulations of more than 15 cc. within the pelvis were rare, and grossly purulent urine was seldom encountered. The inference was that the rapid improvement could be attributed to relieving the kidney of the impediment of stasis.

Comment

When investigations into the pathogenesis of pyelonephritis were first begun, it seemed of primary importance to determine the route by which bacteria reached the kidney. But as studies multiplied and careful observers correlated and interpreted their own and others' work, an interesting new theme appeared and assumed increasingly greater importance. This was a consideration of the situation which might obtain within the kidney and its drainage apparatus to render it more susceptible to infection by whatever route. Previous parenchymal damage and ureteral obstruction, or a combination of both, are the principal determinants. The only other two worthy of mention, apart from the usual general reference to host resistance, are the specificity of certain strains of bacteria and the characteristics of the urine which make it a more favorable culture medium. It might be a matter of no great consequence whether bacteria invading the kidney from the bladder reach it through the blood stream, the lymphatics, or the ureteral lumen or its wall, except that when the last is the case there develops secondarily the important element of obstruction. This derives entirely from local changes, and although it may be attended by altered patterns of neural activity, it is independent of any associated neurological lesion. The significance of these observations, therefore, is not limited to the treatment of patients with spinal cord injury or disease.

Pathogenesis is often considered in terms of a series of morbid anatomic changes, but these rarely develop without associated functional alterations. The development of a disease entity depends no less on pathological physiology than on pathological anatomy. Recognition of this calls for a dynamic rather than a static view of the development of ascending pyelonephritis, a view which is consistent with its ultimate evolution, when the patient faces the hazards of both infection and failing renal function. By the same token, the need for a dynamic approach to prophylaxis and treatment becomes apparent. The progression of pathological changes can often be inferred, and the actual effect of these changes on function followed, by x-ray studies. In favorable cases, measures to relieve obstruction may be instituted. With a normal flow of urine from its pelvis, the kidney is in a favorable position to resist infection, and in particular those infections that arise in the lower tract.

Summary

Pyelonephritis may be hematogenous in origin, but when it follows infection in the bladder, ascent through the ureter is more probable. The subepithelial tissues of the bladder, ureter, and kidney pelvis provide a direct route of invasion which is continuous with the interstitial tissue of the kidney.

The susceptibility of the kidney to infection is markedly enhanced by obstruction. Functional obstruction of the ureter may develop when its wall is involved in inflammatory changes. It is no less a factor than mechanical obstruction would be. The functional changes can be followed, and the underlying process inferred, through serial x-ray studies. The maintenance or reestablishment of adequate drainage of the renal pelvis is a most important factor in the prophylaxis and treatment of ascending pyelonephritis.

DIAGNOSIS AND MANAGEMENT OF THE RARE CAUSES OF GASTROINTESTINAL HEMORRHAGE

James V. Maloney Jr., M.D., Los Angeles

About 10% of all cases of gastrointestinal bleeding involve rare lesions, the treatment of which depends on the exact location of the source of blood. Treatment of existing shock is the only thing that should receive precedence over the taking of a complete history and physical examination. The essence of the treatment of active bleeding is rapid transfusion of enough whole blood to restore normal circulation. The fear that this may make the bleeding worse is unfounded, and the amount of blood needed to restore normal vital signs affords a measure of the rate of blood loss. Nonmanipulative roentgen examination of the gastrointestinal tract need not be deferred for fear of recurrent hemorrhage. If there has been no hematemesis it may be assumed that the bleeding point is below the duodenojejunal junction, and in that case sigmoidoscopic examination and barium enema are essential. Laprotomy with complete examination of the abdomen has failed to reveal the site of bleeding in from 17 to 45% of cases; among the special techniques available in such cases are wide gastrotomy, transillumination, and operative endoscopy. It is possible to examine the ascending, transverse, and descending colon through a single enterotomy in the middle of the transverse colon. If surgery is undertaken, special attention must be given to the anesthesia to prevent aspiration of gastric contents.

The patient with gastrointestinal hemorrhage represents a problem which is a major challenge to the best diagnostic and therapeutic efforts of the internist and surgeon. Of individuals presenting with upper gastrointestinal bleeding, 80% have peptic ulceration of the stomach or duodenum; 5% have intrinsic gastric lesions, such as carcinoma or polyp; and 5% have portal hypertension with bleeding due to varices. Thus, the common causes of upper gastrointestinal bleeding account for 90% of cases. The remaining 10% are due to rare lesions and are the special subject of this discussion.

Preliminary Examination

The localization of the exact site of bleeding is far more important when dealing with the rare causes of gastrointestinal bleeding than it is when the patient gives a typical history of peptic ulceration. Such is the case because chronic peptic ulceration causes gross scarring and contracture which enables the surgeon to identify quickly the pathology when the abdomen is opened. On the other hand, mucosal polyps, congenital telangiectasis, and benign tumors may produce lesions anywhere along 24 ft. of alimentary canal and may completely escape detection by visual inspection and palpation. Surprisingly enough, disagreement still exists as to how extensive a history and physical examination should be done on a patient who is admitted to the hospital with active hemorrhage. Two recently published textbooks recommend that the patient be wrapped in warm blankets and heavily sedated with morphine so that the disturbing elements of history and physical examination will not prevent the spontaneous cessation of hemorrhage. With this attitude I cannot agree. Statistically, such a patient has between a 3 and 20% chance of becoming exsanguinated. There are few surgical emergencies in which there is a more urgent need for a complete history and meticulous physical examination, both performed as soon as possible. The treatment of shock, if it is present, is the only consideration taking precedence over this preliminary examination.

The history not only must include that of the gastrointestinal system but should be extended to include a detailed history, system review, and social and family history. A history of nosebleeds or the use of medicaments known to be associated with bone marrow depression may be the clues necessary to establish a blood dyscrasia as the cause of the hemorrhage. As the clinical experience and confidence of a physician increases, he is likely to forget the dictum taught to medical students: "Seventy per cent of useful diagnostic information comes from the history, 20% from the physical examination, and only 10% from special laboratory tests."

Similarly, the minute details of the physical examination are important. A small supraclavicular node or rectal shelf may identify the source of bleeding as gastric carcinoma. A cutaneous spider somewhere

Read in part at the Postgraduate Course on Pre- and Postoperative Care, Clinical Congress of the American College of Surgeons, San Francisco, California, Oct. 9, 1956.

on the body may be the only hint of liver disease with bleeding due to esophageal varices. In my series of cases, an 8-year-old boy passed large quantities of blood per rectum and was admitted to the hospital in profound shock. During the course of the physical examination, several purpuric spots were noted in the gluteal region, an area of the body frequently neglected in the examination of a patient sitting or lying in bed. In this case, barium enema, gastrointestinal series, endoscopy, and other diagnostic tests would have been as fruitless as an operative inspection and palpation of the patient's gastrointestinal tract. Observation of the purpuric spots led to a diagnosis by blood smear of idiopathic thrombocytopenic purpura, and the patient was cured by an emergency splenectomy.

When all gastrointestinal bleeders are considered as a group, the minutiae of a detailed history and physical examination may be rewarding in only a relatively small percentage of cases. However, in that 10% of patients having one of the rare causes of gastrointestinal bleeding, a significant portion of them will be spared the delay and inconvenience of extensive diagnostic tests.

Immediate Treatment

In the treatment of the actively bleeding patient, the most important determinant of the patient's future therapy is the rate of bleeding. In my experience the patient's estimate of the amount of blood vomited or passed per rectum is unreliable. Moreover, the volume of blood vomited or passed per rectum may be a poor reflection of the total volume lost from the circulation but retained within the intestinal lumen. A somewhat more objective evaluation of blood loss can be obtained by a consideration of the known association of clinical signs with percentage reduction in blood volume. The loss of 20% of the circulating blood volume may be expected to produce tachycardia, narrowed pulse pressure, mild hypotension, and the peripheral signs of hypovolemic shock, provided this loss occurs in too brief a time (one to three hours) to be compensated for by hemodilution. (Blood volume=about 7.5% of body weight. Therefore, a 70-kg. [154-lb.] patient showing these clinical signs will have bled 20%×7.5%×70 kg.=1.05 kg., or 1,050 ml.). Larger acute blood losses will produce a greater tachycardia and a more profund fall in arterial blood pressure.

The essence of the treatment of the actively bleeding patient consists in the rapid (preferably within one hour) transfusion of a sufficient quantity of whole blood to restore the clinical circulatory signs to normal. In general, pulse and blood pressure will return to normal at a point when blood volume is approximately 10% below normal. For this reason, a man weighing 70 kg. is given approximately 500 ml. (10%×7.5%×70 kg.=525 ml.) more blood than is necessary to restore the vital signs to normal. Provided this restoration of blood volume is accomplished within one hour, the physician is in an excellent position to estimate the rate of bleeding in milliliters per hour during the next two or three hours. The rate of blood loss into the gastrointestinal tract will be equal to that amount of blood necessary to maintain normal vital signs during the subsequent hours.

Repeated determinations of hemoglobin level and hematocrit value are of little practical value in the presence of massive bleeding, since the process of hemodilution requires many hours and depends on the state of body hydration and other factors. These tests are more helpful in the patient with slow bleeding (less than 100 ml. per hour). Hematocrit determinations are of distinct help in the evaluation of patients with chronic bleeding, since the clinical problem here is the treatment of anemia rather than hypovolemia. The measurement of blood volume by the Evans blue dye technique is a simple procedure, but there are serious objections to its accuracy in the presence of shock, vasoconstriction, and a changing blood volume. The most cogent objection to the use of the dye technique is the fact that the so-called normal values for an individual of a given weight or surface area are based on an average figure obtained from a large population. Even when provided with a measurement of the blood volume in a bleeding patient, the physician has no way of knowing the normal volume for that individual. For these reasons, the readily assessed clinical circulatory signs are the best guide to blood replacement.

The fear that rapid transfusion may reinitiate bleeding which has stopped is unfounded. The slow restoration of blood volume over a period of four or five hours in a massively bleeding patient is undesirable, since the continuing loss of blood into the gastrointestinal tract and the varying clinical signs make it impossible to estimate the rate at which the patient is bleeding. Moreover, prolonged hypovolemia has adverse physiological effects. If the rate of blood administration necessary to maintain normal vital signs is 500 ml. per hour, the physician is dealing with massive hemorrhage. It can be estimated that the patient will have required 3,500 ml. of blood over the ensuing seven hours. Such a volume and rate of bleeding would certainly be an indication for surgery, even if the site of bleeding were not localized. This estimation, therefore, sets the time limits within which the definitive diagnostic tests must be completed.

Special Tests

In addition to the routine urine and blood tests associated with the history and physical examination, a blood smear and bleeding and coagulation studies are done. There are, in addition, a number of special tests which are of assistance in differentiating the common from the rare causes of intestinal hemorrhage.

For many years, barium examination of the upper gastrointestinal tract was deferred for three weeks after active bleeding for fear of recurrent hemorrhage. There are now several large series of cases which demonstrate that the activity of bleeding is in no way affected by the barium meal, provided that manipulation of the abdomen is minimal and judicious. In those patients with hematemesis and not suspected of having esophageal varices, a large Ewald tube (no. 30 F) is passed to remove clotted and liquid blood from the stomach in preparation for the barium meal. The usual nasogastric tube cannot be expected to prevent accumulation of blood in the stomach unless preliminary removal of clotted blood and food residue is accomplished with a large tube. The use of a Sengstaken tube in the diagnosis and treatment of esophageal bleeding is beyond the scope of this discussion.

The sulfobromophthalein test of liver function has been of particular value in eliminating esophageal varices from the differential diagnosis.[1] On the other hand, demonstration of a severe degree of liver impairment by this test does not indicate that the patient is necessarily bleeding from varices. The increased incidence of peptic ulcer in cirrhotic patients is well recognized, and bleeding from alcoholic gastritis and hiatus hernia is not uncommon in association with cirrhosis. Esophagoscopy is considerably more accurate in the demonstration of varices than is the barium swallow done in association with the upper gastrointestinal series. In my experience gastroscopy has been of little value in the massive bleeder, although it is frequently helpful in patients bleeding slowly from rare lesions such as gastric polyp, esophagogastric ulcer, or multiple gastric erosions. In patients who have not had hematemesis to indicate that the bleeding is from above the muscle of Treitz, sigmoidoscopic examination and barium enema are essential.

A long gastrointestinal intubation tube may be helpful in localizing the site of a bleeding benign tumor, provided that acute massive hemorrhage is not a problem. As the tube passes down the intestinal tract under fluoroscopic guidance, repeated samples of intestinal contents are made and examined chemically for the presence of blood.

Operative Management

The operative management of the gastrointestinal bleeder is relatively easy provided that the diagnostic studies have revealed the source of bleeding, or, at the very least, the general area of the intestinal tract in which it is located. It is a general principle that the surgeon should not operate unless the site of bleeding has been identified. An exception to this occurs when it is impossible to locate the site and continuing hemorrhage threatens the patient with death by exsanguination. Unfortunately, this exception is a frequent one.

In a significant portion of patients operated on without a diagnosis, the source of bleeding will immediately be apparent on entering the abdomen. Evidence of peptic ulceration, previously undemonstrated by x-ray, is often apparent in the duodenal region. Excessive venous collateral circulation, gross liver disease, and the elevation of portal venous pressure as measured by a saline manometer may suggest bleeding from esophageal or gastric varices. Even with the whole intestinal tract available for palpation and inspection at the time of operation, the surgeon has a very poor record in finding the source of previously unidentified bleeding. Gilchrist and Chun[2] failed to find the site in 45% of their patients, Stewart and associates[3] in 17%, and Cooper and Ferguson[4] in 33%. When complete examination of the abdomen fails to reveal the source of hemorrhage, there are several maneuvers which are of particular value.

Wide Gastrotomy.—With Spencer[5] I recently reviewed my experience with the use of gastrotomy. In 11 patients in whom the procedure was carried out, the site of bleeding was demonstrated in 10. Although gastrotomy has been criticized,[6] it is my firm conviction that failure to find it useful is due to technical aspects of the manner in which it is performed.[5] A generous 7-in. incision is made on the anterior surface of the stomach in such a manner that no blood from the cut surface of the gastric wall contaminates the lumen of the organ. Deaver retractors and the operator's hands are placed within the lumen of the stomach and an inch-by-inch inspection made of the mucosal surface. Particular care is taken to visualize the junction of the esophageal and gastric mucosa, a common site of ulceration associated with reflux of gastric contents. Gastrotomy is supplemented with duodenotomy when indicated.

Transillumination.—The jejunum and ileum lend themselves particularly well to inspection by transillumination. Although a Cameron light may be helpful, no special equipment is needed. A portable spotlight in a darkened operating room is all that is required. The spotlight is lowered to table height and the intestine is held in the path of its light beam. A folded towel held adjacent to the intestine by an assistant shields the operator's eyes. Figure 1 illustrates the ease with which the interior of the small intestine may be inspected by transillumination. The technique is so satisfactory that intraluminal objects as small as grape seeds are easily visualized.

Operative Endoscopy.—With the use of a 25-cm. lighted sigmoidoscope, it is possible to inspect the mucosa of the entire small intestine from the pylorus to the ileocecal valve. This method is particularly applicable to the distal duodenum which, because of its retroperitoneal location, is unavailable to inspection by other means. After mobilization of the duodenum by the Kocher maneuver, a single enterotomy is made in the third portion of the duodenum, thus permitting inspection of the ampulla of Vater and the retroperitoneal portion of the organ. By telescoping the small intestine on a sigmoidoscope it is possible to examine its full length with use of only three enterotomies. However, operative endoscopy is usually unnecessary in the jejunum and ileum, since in this area transillumination is so satisfactory.

Operative coloscopy is of unique value in the detection of obscure bleeding in the colon. Preoperative barium studies, even by the air contrast technique, will reveal only half of the polyps present, and inspection and palpation are almost as inaccurate.[6b] In patients suspected of bleeding from the lower tract, preoperative preparation of the intestine with neomycin and phthalsulfathiazole (Sulfathaladine) is used. In emergency situations, mechanical cleansing of the intestine combined with a neomycin retention enema will sterilize the colon. The method of coloscopy is illustrated in figure 2. By dividing the peritoneal attachments of the hepatic and splenic flexures of the colon, it has been found possible to examine the entire colon through a single enterotomy made in the midtransverse colon. The rectum and sigmoid are, of course, examined per rectum preoperatively. Alternative techniques of coloscopy have recently been described by Deddish and Hertz[7] and by Shackelford and McGeehan.[8]

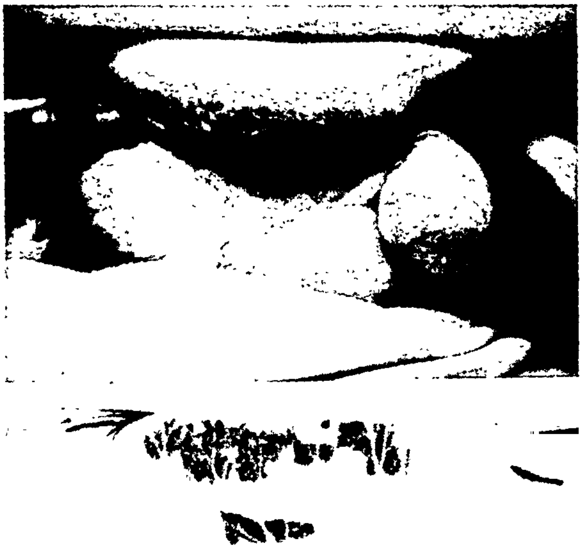

Fig. 1.—Loop of jejunum elevated and back-lighted with spotlight. Folded towel shields operator's eyes. *Top*, before accessory operating room lights are turned off. *Bottom*, after room is darkened.

Blind Gastrectomy.—Several authors have reported that the performance of a so-called blind gastrectomy in the absence of demonstrable pathology will prevent recurrent hemorrhage in a significant number of patients.[9] Success of this procedure depends on the removal of bleeding lesions in the distal portion of the stomach which cannot be detected by palpation or on the reduction of gastric acidity. However, in view of the frequency with which bleeding lesions occur in the upper third of the stomach, it would not appear that blind gastrectomy is always a logical approach to the problem. Many authors have reported patients who have become exsanguinated from a lesion remaining in the proximal stomach after blind gastrectomy.

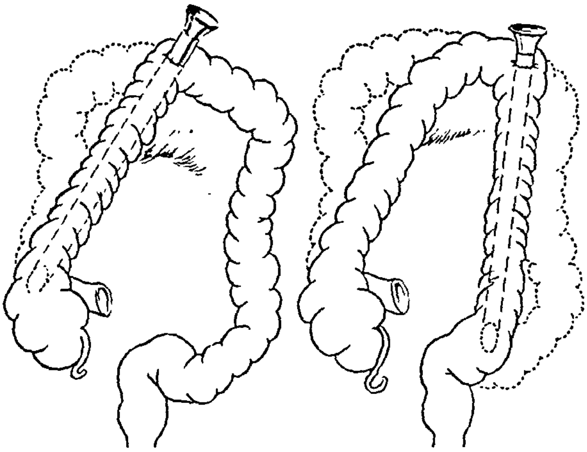

Fig. 2.—Technique of operative coloscopy. After division of peritoneal attachments of hepatic and splenic flexures, entire colon can be examined through single enterotomy in transverse colon.

Gastrotomy.—My experience with gastrotomy was recently reviewed with Spencer.[5] All patients who had been operated on for gastrointestinal bleeding during the preceding 12 months were reviewed. In by far the large majority of cases the bleeding lesion was demonstrated prior to operation. However, there remained 18 patients whose lesions defied our best diagnostic efforts. In seven of these patients the bleeding area was easily located by palpation or inspection when the abdomen was opened. The site of bleeding in the remaining 11 patients was undetermined. These 11 patients satisfied what many would consider the criteria for blind gastrectomy. Instead of performing such a resection, a wide gastrotomy was performed by the technique previously described. The location of the lesions, in three groups, is indicated in figure 3. Blind gastrectomy would have cured with certainty only the three patients in group 1, in whom the bleeding lesion was located in the distal portion of the stomach. There were four patients in group 2 who may, or may not, have been cured, depending on the exact location of the resection. In the four patients in group 3, the bleeding lesion was far up in the gastric remnant or esophagus, and it would presumably have continued to bleed after a blind resection. In addition, the routine use of blind gastrectomy in these cases would have unnecessarily removed the stomach in one patient who had an esophagastric ulcer associated with diaphragmatic hernia and in another patient who had bleeding due to esophageal varices. On the basis of these cases, we believe that a large gastrotomy with definite location of the bleeding point is a more rational procedure than blind gastrectomy.

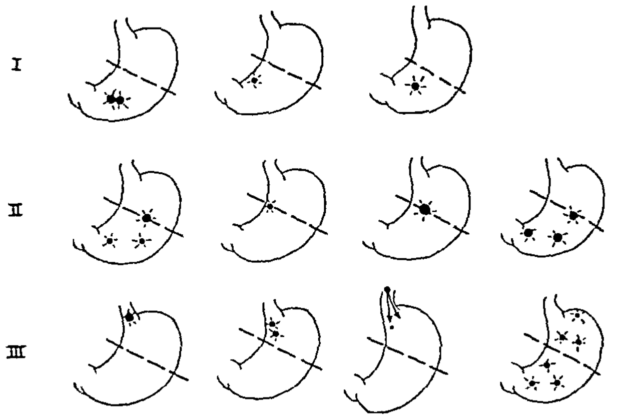

Fig. 3.—Schematic presentation of location of bleeding lesions in 11 patients subjected to large gastrotomy. Blind gastrectomy would have cured with certainty only those patients in group 1.

Despite these criticisms of blind gastrectomy, there are undoubtedly instances where it is valuable. The wisdom of the statement by Osborne and Dunphy[10] on this subject is apparent:

> Although we realize that "blind" gastrectomy may be required because the lesion cannot be identified at operation, we feel that overemphasis of this approach leads to failure to identify lesions which will not be removed by gastrectomy or the performance of this operation for lesions which might not have required it. This is particularly true of the surgeon who has not had extensive experience with the obscure bleeding lesion and who, under the stress of an emergency operation, may overlook a demonstrable site of bleeding because he does not use a systematic examination during laparotomy and fails to appreciate the nature and variety of pathological lesions concerned.

Anesthesia.—A comment regarding anesthetic technique in these cases is pertinent. The presence of blood in the stomach presents a special problem for the anesthesiologist. A distended stomach is a contraindication to the induction of general anesthesia, and active bleeding makes gastric aspiration unreliable. Rapid induction and tracheal intubation with barbiturates and muscle relaxants has had an unfortunate popularity in this situation. The sudden relaxation of the diaphragmatic hiatus with this technique may produce massive regurgitation and aspiration of blood and barium before the endotracheal tube can be placed. An acceptable technique consists in the placement of the endotracheal tube with the patient under topical anesthesia and awake. General anesthesia is begun only after the cuff of the endotracheal tube is inflated. The possibility of aspiration is thus avoided.

Report of Cases

An enumeration of all of the rare causes of gastrointestinal bleeding is beyond the scope of this discussion and, in fact, would be quite impossible. Regardless of the exact nature of the bleeding lesion, the general diagnostic and therapeutic regimen outlined above may be expected to give satisfactory results in the majority of patients. Two cases are presented in brief to illustrate the value of the diagnostic and surgical approach outlined above.

Case 1.—A 54-year-old woman, suffering from gastrointestinal hemorrhage, was noted to have a number of fibromas of the skin as well as a *café au lait* spot in her lumbar region. By the passage of a long intestinal tube under fluoroscopic guidance with repeated aspiration of the intestinal contents, the site of hemorrhage was demonstrated to be just below the muscle of Treitz. A preoperative diagnosis of von Recklinghausen's *neurofibromatosis intestinalis* was made. Operation confirmed the presence of bleeding neurofibromas 1 ft. below the ligament of Treitz (fig. 4, *top*).

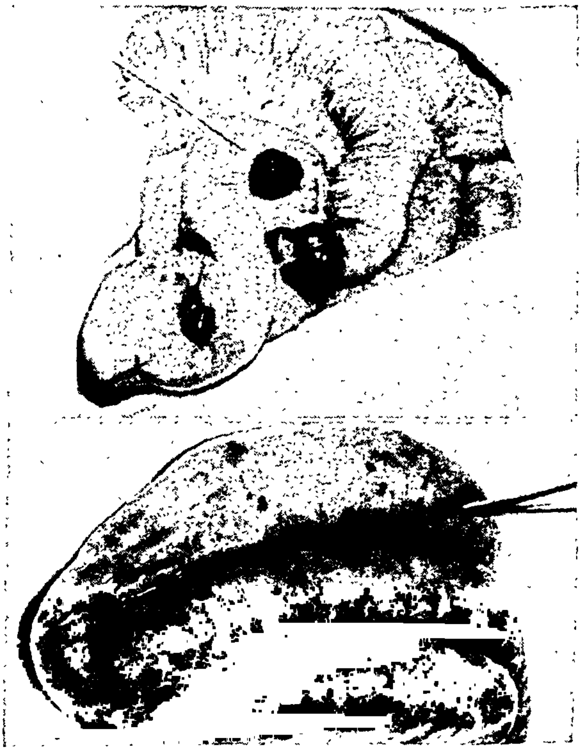

Fig. 4.—Illustrations of rare lesions diagnosed preoperatively. *Top,* intestinal neurofibromatosis (Recklinghausen's disease). *Bottom,* intestinal telangiectasia.

Case 2.—A 14-year-old girl was seen for chronic gastrointestinal bleeding with secondary anemia. The patient's history revealed that she had not yet undergone the menarche, and physical examination demonstrated delayed development of secondary sex characteristics. A preoperative diagnosis of congenital intestinal telangiectasia was made, a condition which has been reported in association with ovarian agenesis. This diagnosis was confirmed at operation where a dilated blood vessel was seen leading to each one of the telangiectatic lesions (fig. 4, *bottom*).

These cases illustrate well the principle that a carefully taken history, a meticulous physical examination, and the judicious use of special tests permit an accurate preoperative diagnosis even in the presence of extremely rare diseases.

Summary

The rare causes of gastrointestinal bleeding account for 10% of all cases of hematemesis and melena and, therefore, represent a surgical problem worthy of careful attention. It is recommended that the physician pursue an aggressive diagnostic program which begins with complete history and meticulous physical examination and includes all routine laboratory work. A judiciously performed x-ray study with barium meal should be done early in the patient's course. It can be expected to give much information and will not adversely affect the bleeding process. The sulfobromophthalein excretion test, esophagoscopy, gastrointestinal aspiration, and other special diagnostic procedures may be indicated by the circumstances in individual cases. Regarding operative management, the most important dictum is that which states that the surgery must be deferred until the source of bleeding is located. It is universal experience that the surgeon is poorly equipped to locate the source of bleeding at the time of operation. However, operation must frequently be performed in those patients who fail to respond to transfusion and in whom exsanguination threatens. Under these circumstances, palpation, inspection, gastrotomy, transillumination, and operative endoscopy are valuable technical aids. Blind gastrectomy may miss a significant number of bleeding lesions in the gastric remnant. A large gastrotomy permits direct examination of the interior of the stomach, the lower end of the esophagus, and the duodenum and offers a more rational operative approach than blind gastrectomy.

Even the physician who approaches the problem of obscure gastrointestinal bleeding with consummate care, wisdom, and skill will encounter some patients who defy diagnosis and die of hemorrhage. It is perhaps some consolation to him in such cases that even the pathologist is occasionally unable to find the source of bleeding at autopsy.

CONTROL OF GASTROINTESTINAL HEMORRHAGE.—Patients with massive acute gastrointestinal hemorrhage can be effectively managed with an initial trial of vigorous transfusion therapy, providing its limitations are strictly observed. These are (1) failure of response to 5 pt. of blood within any 24-hour period; (2) failure of response to any amount within 48 hours, or (3) rebleeding under treatment. Any one of these indicates need for prompt surgical intervention. A relatively fixed mortality rate has been observed over the years for massive acute upper gastrointestinal hemorrhage, despite the increasing availability and use of whole blood. New measures for these patients are needed if mortality is to be lowered. Some help may come from earlier decision about operation, guided in each patient by his response to transfusion therapy.—D. REHABILITATION OF THE PATIENT WITH LONG-TERM RESPIRATORY PARALYSIS

Harold N. Neu, M.D., Omaha

Long-term respiratory paralysis creates problems of rehabilitation. Experiences of a respiratory and rehabilitation center of 30 beds are here analyzed. Twenty beds were reserved for patients with chronic respiratory paralysis. In a five-year period there have been 375 admissions, including readmissions for rechecks, and the 100 patients with the most marked involvement of respiratory and other neuromuscular mechanisms were selected for special study. Such patients require continued care equivalent to that given to the acutely ill patient, and 64 of them arrived in tank respirators. The average period of rehabilitation was 8 months, but some required more than 12. The most frequent complications were renal calculi (detected in 38 patients) and atelectasis (in 36). The best results were obtained when the process of weaning from the respirator was concomitant with rehabilitation instead of taking precedence over it. Although 98% of the patients were freed from the tank respirator, only 16% were freed from all respiratory aid. Five patients died at the center, but 80 were able to return to private home care, and 44 were cared for completely by the family. Sixteen patients who were housewives continued as the dominant figures in their home situation despite continued dependence on respiratory aids. A program of comprehensive care and rehabilitation for this type of patient is economically desirable and has incalculable human values.

Medical science is continually impaled on the horns of dilemmas of its own creation. The development of the tank respirator has occasioned the saving of the lives of thousands of patients who otherwise would have died. At the same time, its use has left in society a large group of respiratory cripples whose pulmonary reserve has been depleted to such an extent that continued respiratory aid of some sort is needed if a reasonably useful life is to be permitted them. There are many others whose pulmonary reserve is adequate to meet the activities of daily living, provided that respiratory infection does not supervene. With the incidence of paralytic poliomyelitis reduced by the poliomyelitis vaccination programs, there is danger that this group of patients will be forgotten by the average physician who attends them, unaware of the further rehabilitation needs of these patients for whom the Salk poliomyelitis vaccine came too late.

In a recent survey, Landauer and Stickle[1] estimated that between 1952 and 1956 there were approximately 9,600 patients with poliomyelitis who had a history of use of respiratory aids during some period of their illness. This is estimated to be 15% of persons with paralytic disease in this period. In their analysis of the poliomyelitis cases reported between 1952 and 1956, they also concluded that 17.4% of the patients were found to have severe paralysis of all eight body areas reported, namely, both arms and both legs, intercostal muscles, diaphragm, trunk extensors, and abdominal muscles. The patient with respiratory crippling is usually further handicapped by loss of muscular power to perform simple activities of daily living.

Respiratory and Rehabilitation Centers

Since 1950, the National Foundation for Infantile Paralysis[2] has aided the establishment of 17 respiratory and rehabilitation centers by assuming the sponsorship and financial help needed for their operation. These centers are located in teaching hospitals that are affiliated with medical schools. They vary in size from units of 15 to 160 beds. Leadership varies from center to center only in that it stems from different disciplines, such as pediatrics, internal medicine, neurology, orthopedics, and physical medicine. The primary purpose of the centers was to stimulate the development and demonstration of techniques and procedures which would enable patients afflicted with severe respiratory difficulties and associated paralysis resulting from poliomyelitis to return as rapidly as possible to normal life. In the past, the life-threatening character of respiratory paralysis dominated the thinking of the physician who treated the disease. He gave little thought to the dilemma which he had created, namely, that of a quadriplegic patient who continued to require respiratory aid. Experience by various centers has demonstrated that maximum rehabilitation is obtained when the first clinician who has seen the patient is aware of the problems that long-term respiratory paralysis can create.

Some of the centers have been located in large metropolitan areas, so that ready referral of patients from acute services could be obtained. In some of these instances, members of a center's team were

Read before the Section on Physical Medicine at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

able to participate in the direction of acute service, a most desirable arrangement. Other centers are located in such a manner that referrals to them come from many states and usually quite a few months after the acute onset. Since there is every reason to believe that there will continue to be isolated patients, particularly young adults, who will contract paralytic poliomyelitis with respiratory complications, I have undertaken to present some of the experiences of one of the centers which is in this latter category. It is hoped that this will stimulate early referral to the centers for such patients and that it will demonstrate the economic value of the comprehensive rehabilitation program for even the patient with severe respiratory involvement and quadriplegia.

The Respiratory and Rehabilitation Center which was established at Creighton Memorial St. Joseph's Hospital, Omaha, in 1953 has 30 beds under its jurisdiction, with 20 of these beds reserved for patients with chronic respiratory paralysis. The usual medical and nursing facilities of a department of rehabilitation, including such co-professional personnel as physical therapists, occupational therapists, medical social workers, vocational psychologists and counselors, orthotists, and speech and hearing therapists, are available for the care of these patients. The direction of the program is under the department of medicine. Consultant services in the fields of neurology, pediatrics, physical medicine, orthopedics, otolaryngology, urology, and psychiatry are utilized in a regular service rotation. A pulmonary function laboratory with a respiratory physiologist in charge is available for the medical evaluation of the respirator patients.

In the approach to the patient, attempts are made to take into account the patient as a whole human being, with physical, mental, emotional, spiritual, social, and vocational problems all interrelated. A team approach, which is physician-directed but patient-centered, is concerned about integrating these various aspects of the patient's problems for his maximum benefit. Multiprofessional staff conferences are indispensable in attaining reasonable goals for the patient. As a result, physician, nurse, physical therapist, occupational therapist, medical social worker, psychologist, orthotist or engineer, vocational counselor, and educational coordinator meet regularly to reach agreement on total patient care objectives and thereby maintain consistent attitudes toward the patient and his family. The Respiratory and Rehabilitation Center has been particularly fortunate in having all of the various disciplines located contiguously. Thus, daily association with each other helps to break down the professional barriers which frequently exist between different professional groups. It also lends to rapid and free communication which is so essential in comprehensive care planning. Benton and Kriete[3] have pointed out that the scope of management of the respirato [illegible]'s knowledge of the field of [illegible]

Source of Material for Study

Since the center opened five years ago, there have been 375 admissions. This includes, however, a number of readmissions of patients for short periods of evaluation some months or years after their initial admission. In order to provide data that were meaningful, 100 patients whose respiratory involvement, and involvement in other body areas, was the most marked were selected for this study. Only the patient's first admission was considered, since it was our policy to keep the patient initially until a satisfactory program for his disposition could be developed or until the staff felt that maximum rehabilitation had been obtained.

In this study, 100 patients are presented for reasons of statistical simplicity. They represent, however, the selection of the most difficult rehabilitation problems we have encountered in our experience. As has been mentioned in previous reports,[4] the patients were brought to the center by air evacuation, ambulance, or train. They tolerated the air evacuation satisfactorily. This method has been most useful in that it greatly shortens the time of transit. Most of the patients came from the states of Nebraska, Iowa, Kansas, Minnesota, and South Dakota, although at least 32 of the group came from 12 other Midwestern and Rocky Mountain states. This factor may have influenced the age distribution of our patients, in that parents of younger children may be more reluctant to send them great distances for medical care.

There were 52 males and 48 females in the group. Seventy-four were between 10 and 30 years of age. This adds significance in the rehabilitation process. On the one hand, it is a period of life where physical appearance is a matter of considerable concern and deformity can be threatening. On the other hand, most of the patients were alert and enthusiastic, and their minds had not been greatly damaged by organic changes.

The source of admission for this group of patients was primarily other hospitals, 88 belonging in this category. Twelve patients were admitted from a private home or a nursing home. The hospitals as sources of admission varied from small 24-bed units in isolated rural communities where the patient had been the only one with poliomyelitis to larger metropolitan institutions in which an acute poliomyelitis service had been maintained. In many of the smaller institutions, private duty nurses were required around the clock for the patient even many months after onset, thereby raising the per diem cost for such patients to levels as high as $50 or $60.

Spencer[5] has clearly shown that the ideal program is effected when the staff can establish confidence in the patient and his family during the acute stage, again when it can wean the patient from respiratory assistance in the immediate post-acute stage, and, from this point, when it can proceed into an active rehabilitation program for convalescent respirator patients. In our group of patients, this optimum condition could not be obtained. Figure 1 indicates the distribution of the patients according to the time of onset prior to admission to the center. Sixty-six of the patients had had their acute onset more than eight months prior to admission.

Assuming a modest per diem cost of $20 prior to admission to the center, $1,356,000 had already been spent for the care of these patients. It would be reasonable to assume that this cost would continue for most of them indefinitely unless some attempt at rehabilitation was made. These figures also show that the long-term cost to the respirator patient cannot be thought of in terms of simple custodial care because of the complexity of the mechanical equipment that is required to keep the patient living from day to day. Continued care of the respirator patient without a vigorous program of rehabilitation usually amounts to the same as acute care.

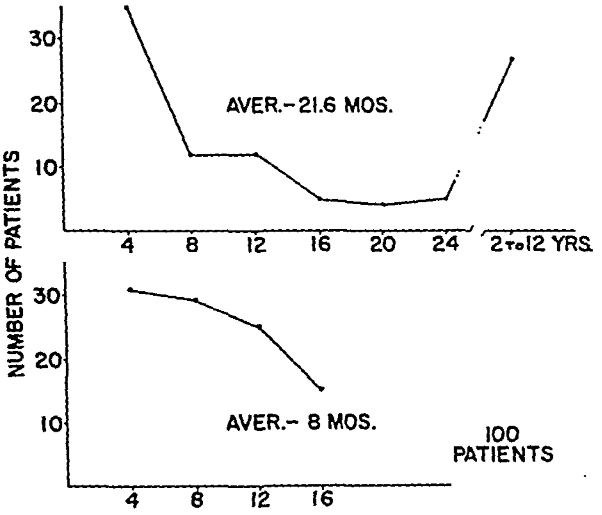

Fig. 1.—*Top,* time of onset of poliomyelitis, in months, prior to admission to Respiratory and Rehabilitation Center. *Bottom,* period of time in center.

Status of Patients on Admission

Respiratory Status.—Of the 100 patients, 64 were brought to the center in a tank respirator, 31 were using a chest respirator, and only 5 had been using a rocking bed at home. The type of respiratory aid used usually correlated with the severity of the patient's physical impairment; however, there were exceptions to this. In a few patients who, on admission, used lesser aids, there was immediate recognition that greater respiratory aid would be required to maintain adequate oxygen saturation and pCO_2 levels. In a few others, the need for hyperventilation was such that although the patient was admitted in a tank respirator he could be very soon weaned to a lesser respiratory aid.

The *vital capacity* is routinely measured in all patients and compared to predicted normals, with use of standards previously described in the literature. In this study, the vital capacities varied from less than 100 cc. up to 1,000 cc. In each of the patients the vital capacity was less than 30% of the predicted normal. Seventy-nine patients were admitted with vital capacities less than 15% of normal.

Affeldt and co-workers,[6] in a study concerning the prognosis for respiratory recovery in severe poliomyelitis, showed that of 500 respirator patients 364 became free of all respiratory equipment within two years of onset. They noted, however, that 83% of these 364 patients were freed within six months after onset. Their study showed that the greatest incidence of removal from respiratory equipment occurred during the second and third months after onset, with a rapid decline thereafter to a low incidence. In the present series of patients, 66 were still in a respirator eight months or more after the onset.

This experience indicates that vital capacity is valuable in determining the need for respiratory aids but it is of much less value in determining when the patient will be removed from respiratory equipment. A rule of thumb which has been found useful is that patients with less than 10% of predicted normal vital capacity will require respiratory aid all the time, in most cases a tank respirator, at least during the night. Patients with vital capacities of 20 to 30% of normal require respiratory aid during part of the day but are able to go unassisted for small periods of time provided that their activities are not too strenuous. Patients whose vital capacities are 40 to 50% of normal may be completely freed of respiratory aid, depending on the breathing pattern their type of paralysis permits them to adopt. Dail and Affeldt[7] have emphasized the effect of body position on respiratory muscle function, and they have pointed out that certain patients breathe best in a supine position and others in the erect or sitting position. A number of these patients with less than 40% of normal vital capacity have been able to get along successfully with a less amount of respiratory aid when they wore a special spring compression abdominal belt which substituted for the paralyzed abdominal muscles.

Physical Impairment Status.—In the survey of Landauer and Stickle[1] previously quoted, the incidence of quadriplegia was 2.5% and paralysis of both arms occurred in 6% and of both legs in 16%. In our group of patients (fig. 2), 80 had quadriplegia, 10 had involvement of both upper extremities, and 5 had paraplegia. In three patients the involvement was spotty, involving many of the eight areas of the body previously mentioned. In two instances, although the extremities were nearly normal, the trunk and diaphragm were markedly involved and the patients required continued respiratory aid.

Since a few patients with types of serious disabilities other than poliomyelitis were also admitted to the center, the staff had an opportunity to evaluate the relative difficulties in rehabilitation management of these different types of disabilities. In their opinion, the traumatic cervical cord injury at levels of C-5 and C-6 provided more difficult problems of rehabilitation than did quadriplegia due to poliomyelitis in a patient who required respiratory aid. The patient with bilateral upper extremity amputation, however, presents less difficult problems of management than does the patient with poliomyelitis with bilateral flail upper extremities together with respiratory impairment.

Period of Treatment in the Center

Landauer[2] has reported that in 1956 the average period of rehabilitation for respirator patients in all the centers was approximately seven months, whereas patients without respiratory involvement required an average of 54 days in the centers. Figure 1 indicates the distribution of patients according to the varying periods of time required in the center for a satisfactory program to be completed. The average period was eight months, although it must be admitted that 15 of the patients required more than 12 months. When one applies the per diem cost of $25 to this group of patients, excluding teaching and research, the cost of the program in the center was $600,000. The Respiratory and Rehabilitation Center forms the hard core of a teaching program in rehabilitation[8]; thus, the costs of patient care, research, and education cannot be easily separated. It is our judgment, however, that this per diem figure represents costs of only basic patient care in the center.

Complications.—In this group of patients, the efforts of the rehabilitation team were frequently delayed or thwarted by varying complications. Dunning and Plum[9] have shown that severe diffuse paralysis is associated with hypercalciuria for periods as long as 50 weeks after onset. In this series, 38 patients had renal calculi detectable by x-ray. There undoubtedly were some others in whom their presence was not recognized except by occasional attacks of renal colic or recurring urinary tract infections.

Atelectasis was the next most common complication, occurring in 36 patients. It required constant alertness on the part of the staff during the winter months, particularly in those patients who had tracheostomy. Experience has shown that early closure of the tracheostomy helps to avoid this complication. The physicians were usually reluctant, however, to do this until the patient had 20-30% of his predicted normal vital capacity. Surprisingly enough, thrombophlebitis occurred in only five of the patients. This may be accounted for by the lower age level of these adults

I have presented elsewhere[10] gastrointestinal complications in this type of patient. One complication, gastric dilatation, was more frequent (occurring in eight patients in this group) than is usually seen in the average hospital population. As a result of experience with this complication at the center, it has been suspected that a number of unexpected deaths of patients with long-term respiratory paralysis in home care situations are secondary to this complication rather than due to the pulmonary insufficiency to which the death is usually attributed. One instance of pneumothorax followed the administration of positive pressure in a manner previously recorded in the literature.[4b] In view of the thousands of times that positive pressure has been used at this center to lessen the decrease in pulmonary compliance in patients with chronic respiratory paralysis, it was felt that this complication was of little significance. Other complications included gastric hemorrhage (five), thrombophlebitis (five), bronchiectasis (two), cardiac arrest (two), peptic ulcer (two), and myositis ossificans (one).

Surgical Procedures.—Many minor procedures, such as tracheostomy, cystoscopy, and others, are performed on these patients. Usually, major procedures are avoided unless it is felt that the procedure will result in a distinct contribution to the patient's rehabilitation. The creation of a useful hand, when possible, in the patients represented a great aid to the rehabilitation program. Therefore, tendon transplant of the opponens was the most common procedure, performed in 11 instances. Nickel and co-workers,[11] in a much larger series, have shown that patients with severe respiratory paralysis can be given the benefits of reconstructive surgery without too much risk, providing a team is available to handle the respiratory complications. Resection of the iliotibial band was done in one instance.

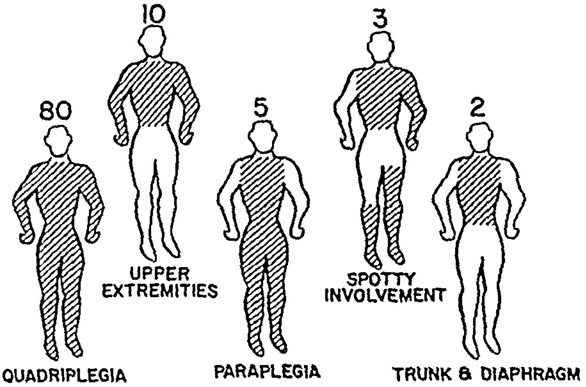

Fig. 2.—Physical impairment status of 100 patients on admission.

Most of the other procedures were urologic, done with the hope of developing methods of solving the problem of renal stones. These procedures included nephrectomy (one), cholecystectomy (one), pyelolithotomy (two), and cystolithotomy (four). After five years of experience, the urologic consultants reserve their procedures for those patients whose progress in the rehabilitation program gives definite promise of few recurrences of the renal complication.

Lobectomy as performed in one patient has been reported elsewhere.[12] This patient was the first one admitted to this center. It is interesting to note that he continues in a home care program five years later, although his vital capacity is less than 600 cc. In rehabilitation centers, the surgeon, except for the orthopedist and urologist, is often forgotten as a contributing member of the rehabilitation team. This may mean losing skills which are of great advantage to the patient.

Effect of the Center Program

When the Respiratory and Rehabilitation Center was established, there was considerable emphasis on the importance of freeing patients from any respiratory aid. Weaning programs were set up with this specifically as a goal. As the staff gained experience, it became apparent that one should sacrifice weaning speed when necessary to allow neuromuscular rehabilitation to proceed concomitantly. It is obviously more desirable to have a well-adjusted, clear-thinking individual using respiratory aid than to have a chronically underventilated, tired, stressed, and irritable patient who breathes unaided.

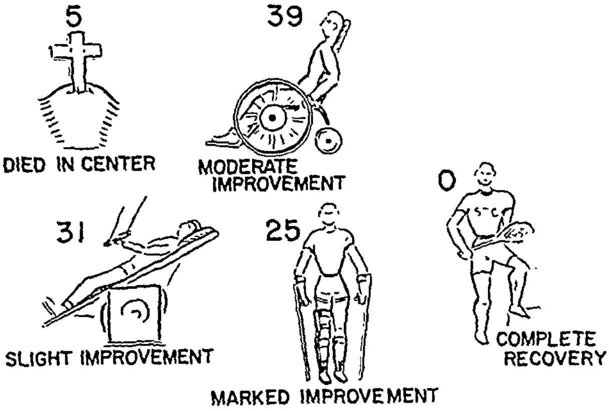

Fig. 3.—Effect of center's program of treatment on ability (100 patients).

Riley and Batson [13] have pointed out that success in weaning from respiratory aids is dependent on many factors, most important being the degree, extent, and distribution of paralysis. They noted that only 1 of 13 patients with more than 90% paralysis was completely freed of respiratory aid.

In the present series of patients, only 16% were freed of all respiratory aid. Ten per cent had their status unchanged. In 37% of the patients, the respiratory aid consisted only of a rocking bed at night. This was usually the case in the patient who had 25-30% predicted vital capacity but whose diaphragmatic paralysis was nearly complete. Some of the studies on such patients during sleep suggested that the arterial oxygen saturation declined and the carbon dioxide levels increased significantly, thereby placing the patient in a deficit from which he had to recover during the daytime.

Most striking, however, is the fact that 98% of the patients were freed of a tank respirator—an important gain, since it was often unsatisfactory to plan home care programs when tank respirators would be required in the home. Those patients who required more respiratory aid than was provided alone by the chest respirator or rocking bed could be managed with a rocking bed which was synchronized with a chest respirator. Only two of the patients required this special equipment.

The effect of the center's program on lessening disability or, conversely, the improvement of ability was more difficult to quantitate. Although use of a personal care rating scale and vocational rating scale, such as advocated by Hoberman and Springer,[14] would have been preferred, it was felt that the uniformity of the disability of the present series of patients was such as to not lend itself readily to such scales. Therefore, the improvement of ability was graded in terms of slight, moderate, marked, and complete recovery. It should be noted that figure 3 refers to the effect on ability. The lessening in physical impairment was in most instances slight, in some moderate; but where such factors as ability to perform some activities of daily living, use of adaptive devices, psychosocial adjustment, and a sense of a realistic goal were taken into consideration, the improvement in ability may be listed as is reported here. Thirty-one of the patients showed slight improvement, 39 moderate, and 25 marked. There were no complete recoveries.

In this group of patients, five died at the center. One patient died of pyelonephritis and hypertensive encephalopathy. A second patient died after resection of the iliotibial band. This death was due to cardiac arrest at the time of surgery. A third patient died after acute gastric dilation, despite all attempts to correct the severe distention and electrolyte imbalance created by this complication. A fourth patient had previously had a nephrectomy and subsequently developed pyelonephritis and a perinephritic abscess in the remaining kidney. The fifth patient was brought into the center in the last month of pregnancy with toxemia and congestive heart failure. This case was unusual in that a postmortem cesarean section was performed and, despite the severe hypoxia to which the patient had been subjected during the last trimester of her pregnancy, a live, normal infant was delivered who now, two years later, gives no evidence of any prenatal injury.

Disposition of Patients

Figure 4 indicates that, even with patients as severely paralyzed as this particular group, it is possible to return 80% of them to private home care programs. This point will be mentioned again, but the enormous saving in patient care costs which has resulted from the change from a hospital per diem cost to a home care program cost more than justifies the efforts of a specialized center. As Landauer [2] has pointed out, the best available patient care is the most economical in the long run and inadequate care is wasteful and expensive. The economics of the Respiratory and Rehabilitation Center are important considerations, but a detailed review of the 100 patients and specific case histories would be necessary to give the full picture of the humanitarian values that can be accomplished by this type of rehabilitation program.

Home Care Programs.—It was recognized from the onset that medical social service would be of great importance in coping with discharge plans of patients with severe, complex disabilities. Furthermore, the varied locations of the patients admitted to this center required that a medical social worker spend much time in travel. Prior to the discharge of each patient, the medical social worker surveyed the local resources of the community, the family, and the available medical facilities. Her visits did much to prepare a sound home care program. In a previous survey [15] of 35 patients, the manner and ease with which severely disabled patients could be integrated into home care situations, at much reduced cost to society, were impressive. Furthermore, an analysis of the day by day activities of that group of patients revealed that they were leading not only active lives but useful ones.

The stability of home care programs depends on three factors: 1. The degree of self-acceptance and acceptance of others which the patient is able to attain. The stay in the center, week-ends spent in the home environment, and local trips to shows, games, and other activities prepare the patient for the time when he must go home. 2. Acceptance of the patient by the family. This is achieved by unlimited visiting hours, regular counseling sessions with members of the family, and periodic home visits before final disposition. 3. Adequacy of the home facilities. This factor requires preliminary visits by the medical social worker, the securing of an attendant, if needed, and the training of an attendant and members of the family concerning the use of respirator equipment.

In a recent questionnaire survey of this group of patients, which was supplemented by data in the medical social service files, it was noted that 44% of this group of patients had no attendant at home but were cared for completely by the family. Thirty-six per cent required full-time attendants and 20% part-time attendants. The staff at this center feels that it is important that the home care situation be not so difficult as to jeopardize the integrity of the family. This point is carefully checked on subsequent readmissions of the patient for short evaluations. The staff is also kept informed by the regional medical social workers of the National Foundation for Infantile Paralysis, who make periodic visits to these patients throughout the United States.

In this recent survey, it was found that 88% of these patients in home situations still receive aid from the National Foundation for Infantile Paralysis. This primarily consisted of payment of salaries for the attendants, maintenance of respiratory equipment, and local medical care for minor supervision that would be needed. Occasionally, however, short periods of hospitalization have become necessary to tide the patient over an upper respiratory infection. Likewise, patients may be readmitted to the center for short periods of reevaluation, usually one or two weeks long, depending on the distance the patient lives from the center. Those in the immediate vicinity are seen on an outpatient basis at shorter intervals. How successful is such a home care program? The recent survey indicates that such programs have remained stable in 80% of cases. As was stated before, the reduction in cost to society more than justifies the economic expenditure on the program of rehabilitation. The gain in human dignity, the example of courage for others, and the maintenance of family strength for unity can only be documented by individual case histories.

Vocational Goals.—The success in attaining proper vocational goals is determined by a number of factors: (1) the natural and educational endowments of the individual; (2) motivation; and (3) vocational opportunity. In the survey of this group of patients, it has been found that 10% are employed full time. Among these are a corporation lawyer who completely supports himself and his family, farmers who direct the operation of their farms, insurance salesmen, magazine subscription salesmen, and others in similar occupations. Ten per cent of the group are employed in part-time activities. These usually are of a home-bound nature or office practice, such as accounting or reception work. Ten per cent of the group could be classified in the student category, in that they are pursuing their academic work in either high school or college. A group that has been of particular interest is the housewives, comprising 16%. They have continued in the role of the dominant central figure in the home situation, despite the fact that they have residual severe paralysis and require respiratory aid.

In 54% of the patients, no vocational goal was realized. That was attributed to a lack of the three factors enumerated. It is unrealistic to assume a vocational goal for a person who has quadriplegia, who requires respiratory aid, and who has an IQ

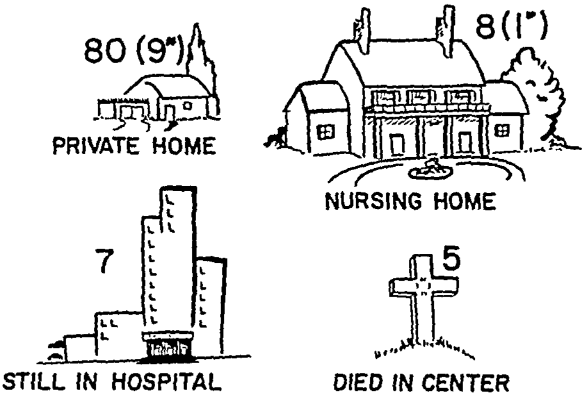

Fig. 4.—Disposition of 100 patients from center (9 died after disposition to private homes).

of 75. In a small percentage, the lack of motivation may have hindered realization of a vocational goal. More frequently, however, the lack of vocational opportunity was responsible. Many of the patients came from small communities scattered throughout many states. Although an excellent liaison was maintained with those state departments of vocational rehabilitation which were satisfactorily organized and as many of the patients were referred to such departments as was possible, experience has indicated that most of these departments were reluctant to undertake responsibility for the severely disabled patients. This was based on the difficulties that occurred in securing proper vocational opportunities for home-bound patients in agricultural areas. As time has gone by, there is improvement in this direction, particularly in some of these states. The placement of a severely disabled patient in a small agricultural community need not be more complex than similar placement in a large urban, industrial area. Considerable education of communities will be needed, however, before this can be accomplished. Emphasis is placed here on vocational goals not because it is believed that they are logical goals for these patients but because they represent the need of every human being to live a useful and productive life. This need should not be destroyed.

Comment

Subsequent readmissions of earlier patients has shown that rehabilitation goals are relative, depending on a number of factors. These are (1) rehabilitation readiness, (2) the growth of skills and competence in the team, and (3) untoward or unexpected complications. In the matter of rehabilitation readiness, it was often noted that the patient had been ill-prepared for the possibility of long-term disability, even though the onset of his disease had been many months prior to his admission to the center. When unrealistic goals had been given the patient, it was found that the rehabilitation process was greatly retarded. This occurred so regularly that most of the staff could predict its occurrence soon after the patient was admitted. This experience emphasizes that nearly all patients faced with the prospect of catastrophic disability react with severe depression at some phase in their illness. This depression may be manifested in different ways, depending on the personality structure present prior to the onset of the catastrophe. There is no simple rule of timing which enables one to predict the development of self-acceptance.

The second factor, namely, growth in competence and teamwork of the staff, was accomplished by the spirit of interchange and collaboration that has existed between the various centers. This was fostered by annual conferences on physiological, clinical, and psychological research on patient care and administrative problems.

The third factor, untoward or unexpected complications, continually plagued the Respiratory and Rehabilitation Center staff. This was particularly true during the winter months, with the attendant respiratory complications, and during the hot summer months, with the genitourinary and gastrointestinal complications. During the past winter, the Asian influenza epidemic resulted in problems of management for a few patients, although the center's population, as well as those who had been previously released, were protected by vaccination.

Summary

Although the Salk poliomyelitis vaccine has greatly reduced the incidence of poliomyelitis with respiratory involvement, there remains a group of respirator patients with long-term disability who will constitute the residue of epidemics for some years yet to come. A program of comprehensive care and rehabilitation for this type of patient is economically feasible and desirable.

A group of 100 respirator patients with long-term disability were studied to ascertain the value of a specialized center for the care of this type of patient. Vocational goals and home care programs may be realistically planned for the rehabilitation of such patients. The teamwork and skills required for the management of the patient with long-term respiratory paralysis are transferable to the care of those with lesser disabilities.

THE PATIENT AND PHYSICIAN IN CARDIAC SYMPTOM FORMATION

ANGINAL SYNDROME

William N. Chambers, M.D., Hanover, N. H., Joseph L. Grant, M.D., White River Junction, Vt.
and
Kerr L. White, M.D., Chapel Hill, N. C.

In the past 15 years there have been numerous articles concerning the role of the physician in causing symptoms and disability, particularly in relation to the heart.[1] The term "iatrogenic disease" is common. It has been stated that physicians may be potent mobilizers of anxiety in patients and may often initiate disabling illness by poorly considered remarks, acts, or unjustified restrictions. Physicians are warned to be cautious in what they say or do before patients and are admonished to avoid the slightest misunderstanding, lest they set in motion the progression of symptoms which will eventually result in the invalidism of a previously healthy person.

This study is an attempt to evaluate the part of both patient and physician in the formation of symptoms suggestive of angina pectoris, especially in patients with normal hearts. Our interpretation indicates that the majority of such patients have neurotic patterns well established and that excessive concern with their hearts already has taken place by the time a physician is consulted. However, the doctor may fail to recognize that the symptoms are primarily related to anxiety and, as a result, may misinterpret them. In a surprisingly large number of instances, the diagnoses of angina pectoris and even myocardial infarction are made when in reality there is no heart disease. The physician erroneously confirms the patients' fears about their hearts and makes the task of dislodging these fears more difficult. On the other hand, the physician may fail to make the diagnosis of coronary artery disease, when it is present, because of the bizarre nature of symptoms which do not fit the rigid clinical criteria for the syndrome.

This study is an attempt to evaluate the part of both patient and physician in the formation of symptoms suggestive of angina pectoris, especially in patients with normal hearts. The data indicate that the majority of such patients have neurotic patterns well established and that excessive concern with their hearts already has taken place by the time a physician is consulted. However, the doctor may fail to recognize that the symptoms are primarily related to anxiety and as a result may misinterpret them, making a diagnosis of angina pectoris or myocardial infarction, when in reality there is no heart disease.

Method

Fifty-five consecutive patients with chest pain were studied and followed during a six-year period. Earlier observations on this group of patients have been published.[2] Each patient had a thorough his-

(Dr. Grant); and Associate Professor of Medicine, University of North Carolina (Dr. White).

tory and physical examination, routine laboratory studies, and x-rays of the chest, gallbladder, and upper gastrointestinal tract. Master's two-step test was performed on all patients who did not have electrocardiographic evidence of myocardial infarction. Other studies were obtained when indicated. Social and personal data were secured from the patient, his relatives, social workers, and hospital records. Because the community is rural and the population relatively stable, in many instances the medical records of the patients' entire lives were available for study. Psychological evaluation was carried out by psychodynamically oriented interviews. A minimum of two hours and, in most cases, more than four were spent with each patient, in addition to time required for the medical aspects of diagnosis, treatment, and follow-up. The factors resulting in the development of symptoms interpreted as "heart disease" and the attitude of the patient and his doctors toward his condition were carefully recorded. An attempt was made to evaluate the patient's and the physician's part in the development of these cardiac symptoms.

There were three groups: 1. Twenty-five patients had classic angina pectoris for at least six months followed by a well-documented myocardial infarction. 2. Twenty-seven patients had cardiac neurosis; they complained of chest discomfort and other symptoms which they referred to the heart, but clinically there was no evidence of angina pectoris or other heart disease. 3. A third group of three patients had chest pain suggesting one of the first two diagnoses but not completely fulfilling the criteria for either. This paper will consider the patients in the first two groups.

The original study was completed six years ago. At that time there were 20 patients in the angina pectoris group, 20 in the cardiac neurosis group, and 15 in the third group. It has since been possible through follow-up studies to clarify the cause of chest pain in 12 of the 15 patients in the third group. Seven of these patients have been put in the cardiac neurosis group and five in the angina pectoris group. None of the patients originally classified as having cardiac neurosis or angina pectoris were changed. Eleven of the patients with angina pectoris have died. No patients in the cardiac neurosis group have died.

Results—Cardiac Neurosis

The Patient's Role in Cardiac Symptom Formation.—Direct reference to the heart was made by 19 of the 27 patients in the cardiac neurosis group on first consulting the physician. These patients were convinced that they had heart disease despite no previous contact with a doctor. Although the other eight patients did not refer directly to their hearts, they complained of chest pain and further questioning showed that they also had long-standing and excessive fear of heart disease. When these patients with cardiac neurosis were seen later in consultation, 15 who had never been told they had heart disease by their referring doctors were as convinced that they had heart disease as the 12 patients who had repeatedly been told erroneously that they had heart disease. Six patients inferred from their physician's comments that they had heart disease. Eight patients made statements which careful documentation has established as extreme exaggerations concerning what their physicians had told them about their hearts, and four patients definitely misrepresented facts.

The average number of doctors consulted by each patient in the cardiac neurosis group was 4.7 compared to only 1.5 for each patient with angina pectoris. The patients in the former group went from doctor to doctor seeking satisfactory explanations of their symptoms and attempting to obtain confirmation of their beliefs that they had heart disease. Many of these patients had been referred to the investigators for further medical consultation because they had not been satisfied with the original opinion that they had normal hearts or because their physicians were uncertain of the diagnosis. Eight patients had been seen by six or more physicians concerning their heart complaints. Seventeen patients had been referred one or more times by their own physician for further opinion. Fourteen patients sought other opinions by going from doctor to doctor without being referred. It was not unusual for these patients to be consulting a number of physicians simultaneously for opinions and treatment, apparently deriving different satisfactions from each. Several patients in the group maintained a balance between their family physicians, who treated them with cardiac drugs, and the consultants, who did not agree that they had heart disease. One of these patients, who had been seen by one consultant for several years, changed to another consultant who accepted her need for believing that she had heart trouble, when the first physician became insistent that she did not have heart disease. It was apparent that, if a patient had been studied a number of times with varying diagnoses, the positive diagnosis usually was given by the patient. If the final opinion was that the patient's heart was normal, these patients insisted all the more that they did have heart disease despite attempts at reassurance.

Ninety per cent of the patients in the cardiac neurosis group had a strong tendency to dramatize their symptoms. They described these graphically and referred to their "heart disease" or "heart pain." This was in striking contrast to the patients with angina pectoris, who often tended to deny their complaints and seldom talked directly about their hearts. The phobic, hysterical, and hypochondriacal tendencies observed in the former group of patients were marked. It was also apparent that they had experienced intense anxiety throughout their lives. The anxiety was focused with varying degrees of intensity on the heart. In some patients, under certain circumstances this would shift from the heart to other organ systems. Such patients tended to identify with relatives, close friends, associates, or public figures who had, or who were thought to have had, heart disease. These relationships often were not close.

The onset of chest pain in every patient with cardiac neurosis was preceded by increasing emotional tension and was often associated with deterioration in the life situation. Usually, there was a superimposed threat to his interpersonal security at the time the symptoms developed. In 17 of the 27 patients with cardiac neurosis, 18 definite organic conditions not related to the heart contributed to the chest pain. Similar organic lesions failed to produce pain in six other patients in the group. In 10 of these patients with cardiac neurosis, no anatomic disease was found by the diagnostic means employed. It was apparent that a consideration of organic pathology alone was inadequate to understand completely some of the patients' "anginal" pains and their anxieties.

The patients with cardiac neurosis showed a high degree of secondary gain. In some, the pain represented a mechanism for setting limits to their activities and freed them temporarily from intense pressures or responsibilities. It seemed to act as a means of getting attention and of controlling immediate members of the family. In others, the pain represented an acceptable "excuse" for failing to attain life objectives. Monetary compensation played a large part in six patients who had been discharged from military service with an incorrect diagnosis of angina pectoris and in one patient in civilian life. All of these patients had regressed to markedly dependent states of existence. When the diagnosis of heart disease was not confirmed and withdrawal of compensation became imminent, these patients uniformly became resentful and continued to insist on the presence of heart disease. One patient in this group collected testimonial statements from his friends, many of them sworn and notarized, to prove the presence and the severity of his chest pain. A second patient, a 25-year-old steamfitter who had received 60% compensation for four years, was evaluated completely at a Veterans Administration hospital; the diagnosis of coronary artery disease was not confirmed, and his compensation was revoked. Being dissatisfied, he gained admission to another VA hospital, where the diagnosis of angina pectoris was made, and the compensation was reinstituted. A 50-year-old conductor and morphine addict had received compensation for coronary artery disease for 10 years. On review of the problem, the diagnosis was not confirmed and his compensation was revoked. Two days later, while on leave from the hospital, he committed suicide.

The Physician's Role in Cardiac Symptom Formation.—Four of the 27 patients in the cardiac neurosis group developed abnormal anxiety concerning their hearts only after being told by their original physicians that heart disease was present or suspected. In these patients, the physicians' attitudes were considered the primary factors in mobilizing anxiety and aggravating symptoms, either by excessive concern over the complaints or by evident doubts about the diagnoses.

The remaining 23 patients in the cardiac neurosis group had an abnormal degree of anxiety concerning their hearts before visiting their doctors. In 12 of these patients the fears were confirmed and increased when they learned that heart disease was, indeed, present or suspected. With each of these patients it is considered that the physician's role was of secondary importance in mobilizing anxiety and symptoms related by the patient to his heart.

In the 23 patients with angina pectoris, none were found in whom a physician was considered to be a primary factor in the production of symptoms, but in 4 patients it was considered that physicians did augment the patients' fears by their attitudes.

Although abnormal anxiety about heart disease appeared to have originated within the patients, it was unwittingly encouraged and augmented by physicians. Of the 27 patients with cardiac neuroses, 12 had been told previously, by two or more physicians, that they had "heart trouble." A diagnosis of myocardial infarction had been made in eight of these patients, and they all had been treated for this condition one or more times in civilian or VA hospitals.

In reviewing the past records, it was noted that in the same patient the diagnosis of coronary artery disease was made repeatedly by some physicians and denied by others. The family physicians had made a diagnosis of coronary artery disease 12 times in these eight patients, whereas a diagnosis of no heart disease was made only once. The consultants made diagnoses of coronary artery disease three times and of no heart disease five times. Physicians in the armed forces diagnosed coronary artery disease four times in these patients, although they diagnosed no heart disease six times. Physicians in the VA hospitals made a diagnosis of coronary artery disease eight times. No evidence of heart disease was found in any of these patients during the final evaluations.

CASE 1.—In a 50-year-old loom fixer, a diagnosis of coronary artery disease had originally been made during military service in World War II but was denied during the same year at two different military hospitals. The following year a diagnosis of coronary artery disease was made by the family physician. Subsequently, a diagnosis of heart disease was made by the consulting cardiologist. The same patient presented himself in 1947 and 1951 at VA hospitals with the same complaint, but no evidence of coronary artery disease was found on either occasion.

CASE 2.—A 42-year-old accountant was treated for acute myocardial infarction in 1951. Review of his record showed that he was studied at a military hospital during his service three different times between 1942 and 1945 for complaints referred to the heart but no heart disease was found during each of these three periods of study. Subsequently, this patient was studied at the VA hospital on two separate occasions in 1956 for the same complaints, and again no evidence of heart disease was found.

CASE 3.—A 52-year-old public relations expert was originally told by his family physician that he had coronary artery disease in 1941. This diagnosis was later confirmed at a VA hospital five times in 10 years. A diagnosis of angina pectoris was made at a large medical clinic in 1946. However, no evidence of heart disease was found in the same patient in another large clinic in 1952, as well as at the VA hospital in 1950, 1955, and 1957.

Results—Angina Pectoris

Although there was less confusion concerning diagnosis in the 25 patients with organic heart disease, many difficulties were encountered here also. This was often because of the extreme degree of denial, insistence on continuing physical activity, atypical nature of symptoms, and, frequently, the patient's failure to consult the physician for some time after the onset of symptoms. Incorrect interpretation of the electrocardiogram was a further source of mistaken diagnoses.

The need for careful evaluation of symptoms and findings and for other consultations often accentuated the concern of patients who originally had not focused on their hearts but had even denied their symptoms. As time went on, these patients frequently came to observe every minor bodily sensation. One patient who originally had completely denied his symptoms gradually became excessively concerned during several weeks of indecision and study by the physician. Waking himself at night to record symptoms in a diary, he also kept elaborate charts indicating episodes of pain, all carefully marked with red and black pencils. Finally, with clarification of the diagnosis and the outlining of a specific program, his anxiety decreased and he returned to more normal activity.

Other patients with coronary artery disease were overtly terrified and behaved as though any physical or emotional strain was too great for them. They seemed to have "wrapped themselves in cotton wool." Three patients in the group manifested an exaggerated form of this behavior. No encouragement or reassurance was of any avail in freeing them from their fears or helping them to return to more normal and productive lives. These three men all assumed passive roles in their households, managing some of the domestic duties while their wives went out to work. Even though they were preoccupied with their extreme disabilities, they continued to deny that their pains were due to heart disease and insisted that they were due to indigestion or some other noncardiac cause. In contrast, many patients continued heavy physical activity after their initial episodes of coronary thrombosis despite the urgent advice of the physicians to the contrary.

Many of these patients seemed to work through various stages of inability to adjust to their diseases as manifested by either denial or invalidism, but then they finally accepted it and lived constructively within their newly imposed limits.

The severity of angina pectoris definitely appeared to be altered in many instances by the physician's attitude and by supportive psychotherapy. This was particularly apparent in three patients who were originally incapacitated more by fear than by pain but who gradually were emancipated through careful management and finally were able to carry on active lives.

Atypical chest pains and other symptoms in patients with known angina pectoris presented difficult and confusing problems. Striking differences often occurred in ability to perform physical activity. At times, a patient was able to plow an entire field with no pain, whereas, on other days, merely bending over induced an attack of angina. The atypical chest pain often misled the physician in the management of the patient. There was often failure to recognize that patients with angina pectoris may also have severe degrees of cardiac neurosis with excessive concern about their hearts. Another source of difficulty in diagnosis was the presence of other organic lesions which could also be associated with chest pain. One patient was convinced he had angina pectoris. His physician refused to make this diagnosis and insisted that the pain was due to a hiatus hernia. The patient then went to a large clinic where a definite diagnosis of coronary artery disease with angina pectoris was made. The patient returned to his original physician who angrily denounced the clinic and its opinion and stated, "I am still convinced that you do not have heart disease." The patient then changed to a physician who agreed with the diagnosis of angina pectoris.

Comment

From this study of 55 consecutive patients with chest pain, it is apparent that many are convinced that they have heart disease even though it is not present. These patients have a well-developed group of symptoms which they refer to the heart despite the fact that they have had no previous contact with a physician concerning this problem. They have a tendency to consider that any discomfort or pain in the chest denotes heart disease. They dramatize their symptoms and identify with other people with heart disease. Their fears are augmented when they are under increased emotional tension, particularly when there are threats to interpersonal security. The degree of incapacity resulting from such "heart disease" varies, depending on the personality of the individual and his needs at the specific time. Some are totally incapacitated, whereas others are able to lead an active and constructive life in spite of their symptoms. Patients who have received various types of compensation because of their heart disease often regress to a complete state of invalidism. If this compensation or the need for invalidism is questioned, they become angry and defensive and use many methods to insure continuation of the compensation. Once an individual has allowed himself to regress to this stage of dependency, it is difficult or impossible for him to relinquish this way of life even though the diagnosis of heart disease has been disproved. Their eventual incapacity equals the most serious types of heart disease. Sudden withdrawal of long-continued compensation may be disastrous. It seems highly probable that the conviction that they have heart disease may be essential for the functioning of some patients in life at certain times. It may represent a necessary defense against potentially overwhelming anxiety. Under these circumstances it is often advisable to allow the patient to maintain his cardiac neurosis even to the point of continuing some form of cardiac regimen.

The concept of iatrogenic heart disease stresses the culpability of the physician in the initiation of the cardiac neurosis. Our data suggest that only rarely does the doctor actually provoke the earliest symptoms of this disorder. We are aware of the potential role of the physician's remarks and attitudes in the formation of symptoms and in increasing fears and disability in patients. However, during this study we became aware of the frequency with which patients' excessive fears and convictions concerning their heart disease occurred before there had been any contact with a physician. We have no intention of justifying the physician or condoning his errors in diagnoses, but we do believe it is important to recognize that the source of the cardiac neurosis lies in the patient's, not the doctor's, personality. There appears little basis for the uncritical acceptance of the prevalent concept of iatrogenic heart disease. We are in agreement with Hart,[16] who stated that, in cardiac neurosis, heart symptoms are present long before the allegedly iatrogenic statement or suggestion.

The physician is often responsible for serious mistakes in diagnosis and treatment of patients with chest pain, frequently making a diagnosis of angina pectoris and even myocardial infarction when no heart disease is present. He may also aggravate preexisting abnormal anxiety about the heart by evident doubt about the diagnosis or excessive concern over the patient's symptoms. Furthermore, the physician must recognize that his opinion concerning the diagnosis may be only one of many to which the patient is exposed. This may be either because the patient voluntarily changes physician or because of the nature of modern medicine in which the patient's medical care is fragmented and responsibility is divided between the family physician, several consultants, diagnostic centers, and civilian, military, and VA hospitals. The emphasis is primarily on establishing a diagnosis and not in understanding the patient and his symptoms. In this way there may be repeated changes of diagnoses. In a VA hospital it is not unusual to find that one physician has made a diagnosis of angina pectoris and the patient has been given full disability. On a later hospitalization, another physician, having studied the problem thoroughly, finds no evidence of heart disease and all compensation is withdrawn. Under these circumstances the patient, not satisfied with a diagnosis in one hospital, may gain admission to another where the diagnosis he is seeking is confirmed.

Because of the subtle problems often involved in the diagnosis of angina pectoris, the patient's emphasis on his chest pain and preoccupation with other cardiac symptoms are potent factors which encourage unwary physicians to make the diagnosis of heart disease. Every physician is aware of the difficulty of making a specific diagnosis of heart disease in a patient whose symptoms are not clear-cut and in whom laboratory findings are equivocal. If the physician is not convinced of the diagnosis, it is often difficult for him to convince the patient. We believe that it may be harmful to positively tell the patient that he has no disease when there is doubt. If the patient is anxious already, further anxiety may be mobilized by unwarranted and superficial "reassurance" by the physician. The emphasis must be on a more fundamental understanding of the underlying sources of the patient's anxiety and his conflicts.

The diagnosis of angina pectoris is frequently difficult to make because of either the atypical nature of many of the symptoms or the patient's tendency to deny the presence of pain. Other patients with angina pectoris accentuate their symptoms and become incapacitated because of their excessive concern about themselves. The severity of angina pectoris and the degree of incapacity can be influenced in some instances by the physicians' and patients' attitudes and by psychotherapy. The patient with angina pectoris often has a cardiac neurosis which is equally severe. Such patients may have excessive reactions to their disease and to their physical sensations. The anxiety in turn may augment the frequency and severity of the anginal attack.

It often is thought that a dignosis of cardiac neurosis excludes the diagnosis of angina pectoris or that if angina pectoris is present cardiac neurosis does not complicate the problem. Actually, it is impossible to divide a patient's response in this way. Diagnosis by exclusion is usually difficult and frequently wrong. The real problem is to determine how many of the patient's symptoms are related to coronary artery disease and how many are due to the cardiac neurosis. If the physician can realize that the patient's symptoms are manifestations of his reactions, whether due to coronary artery disease or to neurotic anxiety about his heart, then he will be able to help the patient to make a more satisfactory adjustment. This will not necessarily "cure" the heart disease or the neurosis, but it will help the patient to understand his symptoms and how he can live with them.

Summary and Conclusions

Fifty-five patients with chest pain of anginal type have been studied comprehensively and followed for six years. Twenty-seven of these patients had no evidence of heart disease but were convinced of its presence. The neurotic pattern was well established and the cardiac fixation had already taken place by the time they came to the physician. They tended to dramatize their symptoms and often would refer to their "heart pain." They were all intensely anxious people whose neurotic behavior was readily apparent. In 17 of these patients organic conditions not related to the heart contributed to the pain. Monetary and other forms of compensation were strong forces in prolonging and aggravating the incapacity. They consulted many different physicians, occasionally receiving independent treatment from two doctors at once. All patients were convinced that they had heart disease whether or not they had had previous contact with the physician. These patients often misinterpreted and exaggerated the physician's remarks.

The physician was found primarily culpable in precipitating the cardiac neurosis in four of the patients. The physician confirmed and aggravated preexisting fears in 12 patients. In the remaining 11 patients he was considered to have had no direct effect. The physician often failed to recognize that the symptoms were due to anxiety and, as a result, misinterpreted them. A diagnosis of angina pectoris had been made one or more times in these 12 patients in whom no evidence of heart disease could be demonstrated. Eight patients without evidence of heart disease had been diagnosed as having myocardial infarction 27 times. They were said to have had normal hearts 22 times during the same interval of time. A misdiagnosis in favor of organic heart disease was made most frequently by the family physician. On the other hand, the physician often dismissed the diagnosis of coronary artery disease when in reality it was present because of the bizarre nature of symptoms that did not fit rigid clinical criteria for the syndrome.

The patient with cardiac neurosis has a well-developed group of symptoms which he refers to his heart. He is frequently convinced he has heart disease before consulting the physician. The physician may aggravate the patient's fears by his indecision, incorrect diagnosis, and failure to understand the cause of the patient's anxiety. The physician is often unable to be certain about the differential diagnosis between angina pectoris and cardiac neurosis and is frequently culpable of misdiagnosis in favor of organic heart disease.

The diagnosis of heart disease is often dismissed when actual disease is present because of the patient's behavior and the atypical nature of his symptoms. This confusion is greatly increased when the patient is exposed to several physicians over a number of years, each of whom may have varying opinions concerning the diagnosis. The criteria for the diagnosis of angina pectoris and cardiac neurosis must be reevaluated in the direction of the total individual response and not simply of the disease entity itself.

CARDIAC ARRHYTHMIAS IN EXPERIMENTAL SYNCOPE

Capt. George Dermksian (MC), U. S. A. F.
and
Lawrence E. Lamb, M.D., Randolph Air Force Base, Texas

The frequency with which a history of one or more syncopal episodes is elicited among aviation cadets in a flying training program was found to depend on the circumstances of the questioning. When anonymity seemed to be assured, 15 out of 50 admitted having had previously undisclosed syncope. Carotid sinus massage and certain breathing maneuvers were used to induce experimental syncope. During these procedures 21 of the 50 had one or more syncopal episodes. Arrhythmias were seen in 15 of the 21 who fainted and in 22 of the 29 who did not faint. Cardiac arrhythmias were not induced in any case by respiratory maneuvers after administration of atropine. The experimental procedures were not able to identify the subjects who had previously experienced syncope. The results argue against the supposition that syncope itself indicates an underlying disease state.

Loss of consciousness presents a serious problem to modern aviation and in critical areas of industry. Syncope is commonly seen at the blood bank, during inoculations, in the dentist's chair, and during moments of stress. Although its occurrence is well known, little information is available concerning the likelihood of its recurrence in any individual or its actual relationship to experimental syncope. It is common practice to study the problem of syncope with orthostatic measures utilizing the tilt-table or eliciting well-known reflexes such as the reflex resulting from carotid sinus massage.

Interest in this problem began with the discovery of significant cardiac arrhythmias occurring with simple respiratory maneuvers.[1] Some of these were associated with syncope. The respiratory system must make constant adaptations to changes in the environment associated with flight and altitude exposure. This facet of information as related to syncope seemed worthy of further exploration. Eighty-two apparently healthy persons engaged in flying activity who had experienced syncope were studied,[2] 55 of these with special procedures. It was impressive to note the number of cardiac arrhythmias that occurred in this series, and it was equally impressive to note the relation of cardiac arrhythmias to the experimental production of syncope. Of the group studied by experimental procedures, breathing maneuvers such as breath-holding at the height of inspiration and breath-holding after hyperventilation were most rewarding in illustrating the problem of cardiac arrhythmia as related to syncope.

In the previous study, the subjects evaluated all had admitted to episodes of syncope for which their future flying careers were placed in jeopardy. It was felt that it would be informative to study, by a similar battery of tests, a group of young flying personnel who had previously denied syncope. This also provided an opportunity to more carefully evaluate the role of atropine in both creating and preventing syncope in such a group. Atropine was used in only a few instances in the previous study. This report is based on the studies of this group.

Methods and Materials

Fifty healthy cadets in preflight training were brought to the School of Aviation Medicine for syncope evaluation. They were volunteers who were told only that they would serve as experimental subjects for tests at the School of Aviation Medicine. The nature and purpose of the tests was not disclosed in advance. As an incentive, each was guaranteed extra time off from duty. The cadets represented a relatively young age group. Their age span was from 19 to 27 years, and their average age was 21.1 years.

All of these individuals had denied previous syncopal episodes in order to gain admittance to the aviation cadet flying training program. All subjects had been previously examined. They were subjected to a battery of special procedures to test the cardiovascular system. This included observation of the patient's blood pressure, pulse, and symptoms and signs at rest and on a tilt-table. The subjects performed breathing maneuvers which included (1) breath-holding at the height of maximum inspiration without bearing down, (2) prolonged breath-holding, (3) hyperventilation, and (4) breath-holding after hyperventilation. These were repeated in the standing and recumbent positions. The carotid sinuses were massaged for 15 seconds' duration, and the subject underwent a 15-minute orthostatic tolerance test on the tilt-table. After these procedures, the subject received atropine, 1/50 grain (1.2 mg.), and the respiratory maneuvers were repeated.

Each subject was assigned a number which he selected from a hat. He was not identified by name and was assured that no further attempts would be

---

Clinical Findings in Fifty Persons Subjected to Study for Syncope

Case No.	Age	Clinical History	Experimental Findings
1	20	None	Breath-holding caused shift of pacemaker to atrial focus; subsequent to atropinization,* breath holding failed to produce shift
2	20	Syncope after bilateral carotid occlusion Syncope 3 hr. after immunization	Breath-holding caused shift in pacemaker to atrial focus; once precipitated, other respiratory maneuvers could produce shift; two atrial premature contractions were noted; after atropinization, no arrhythmia was noted
3	22	None	Breath-holding resulted in sinus bradycardia; carotid sinus massage caused marked slowing to 38 beats per minute associated with near syncopal episode; two min. after carotid sinus massage, rhythm changed to nodal rhythm, then to normal sinus rhythm, then to A-V dissociation; hyperventilation followed by breath holding induced atrial rhythm; after atropinization no changes in pacemaker or cardiac rhythm could be induced
4	22	None	No findings
5	23	At age 13 fainted after breaking finger	During base-line studies, when first placed on tilt-table experienced 3 sec. of asystole followed by escape, followed by another 6-sec. period of asystole and escape; after recurrent episodes of asystole, patient developed nodal rhythm, and syncope occurred
6	23	None	Immediately after left carotid sinus massage, felt weak and faint; 2 min. later developed period of asystole followed by syncope; asystole terminated by ventricular escape beat, short period of atrial flutter, and, finally, resumption of normal sinus rhythm; after breath-holding, A-V dissociation with nodal rhythm occurred; after atropinization no arrhythmia could be elicited by breathing maneuvers
7	20	None	No findings
8	20	None	After prolonged breath-holding, change in PR interval to 0.08 sec. with upright T waves in all leads; after atropinization breath-holding produced no changes from normal sinus rhythm
9	20	Syncope at age 12 induced by chest squeeze during breath-holding after period of hyperventilation	Prolonged breath-holding caused change to atrial focus; at height of inspiration with breath-holding, period of second-degree A-V block; prolonged breath-holding followed by episodes of second-degree A-V block and syncope; after atropinization breath-holding produced no changes from normal sinus rhythm
10	20	Syncope at age 18 during chest squeeze in full inspiration after hyperventilation	Breath-holding caused shift to atrial focus and atrial rhythm; breath-holding after hyperventilation induced one ventricular premature contraction; after adequate atropinization, no arrhythmias could be induced by breathing maneuvers
11	20	None	After breath-holding, atrial rhythm appeared; after atropinization no arrhythmia could be induced
12	22	None	After breath-holding there was shift in pacemaker to atrial focus followed by bradycardia which persisted for 2½ min., then A-V dissociation, nodal rhythm, and syncope; after atropinization no arrhythmia could be induced by breathing maneuvers
13	21	At age 16 was sitting with feet on stove; got up, yawned, and passed out	Breath-holding caused a shift in pacemaker to secondary atrial focus
14	20	None	Right carotid sinus massage caused change in pacemaker to secondary site; 2 min. after massage, patient had near syncopal episode; breath-holding caused shift in pacemaker to secondary atrial focus; after atropinization no arrhythmia could be induced by breathing maneuvers.
15	22	At age 20 years, syncope associated with orthostatic hypertension	On release of breath after prolonged breath-holding, one ventricular premature contraction noted; during hyperventilation, one ventricular prematurity noted and after tilt to the horizontal position, one atrial premature contraction occurred; after adequate atropinization no arrhythmias were noted
16	21	None	Right carotid sinus massage caused change in pacemaker to secondary atrial focus; after breath-holding, atrial rhythm and atrial fusion beats noted; breath-holding after hyperventilation produced atrial rhythm with second-degree A-V block, and A-V dissociation with syncope; breath-holding with patient in recumbent position also produced atrial rhythm; after atropinization, breath-holding produced no changes from normal sinus rhythm
17	19	None	With patient first placed on tilt-table to obtain baseline blood pressures and studies, A-V dissociation with nodal rhythm occurred and was associated with syncope
18	21	Syncope at age 18 while marching in sun while ill with influenza	Breath-holding after hyperventilation caused drop in blood pressure with progressive slowing of cardiac rate and syncope
19	20	Syncope at 8 yr., after injection	After prolonged breath-holding, A-V dissociation and nodal rhythm (rate 40/min.), followed by syncope; after atropinization, breath-holding produced no changes from normal sinus rhythm
20	23	None	Breath-holding caused shift in pacemaker to secondary atrial focus; after atropinization, breath-holding produced no changes from normal sinus rhythm
21	21	None	Breath-holding produced immediate slowing of pacemaker and change to atrial rhythm; this was successively repeated with breath-holding; after atropinization, breath-holding produced no changes from normal sinus rhythm
22	21	None	Occasional ventricular premature contractions throughout study
23	21	None	Breath-holding resulted in shift in pacemaker to secondary atrial focus; after atropinization, breath-holding produced no changes from normal sinus rhythm
24	21	None	No findings
25	20	None	Breath-holding caused shift in pacemaker to secondary site; after atropinization, breath-holding produced no changes from normal sinus rhythm

Clinical Findings in Fifty Persons Subjected to Study for Syncope—continued

26	20	None	Left carotid sinus massage followed by sinus arrest with modal escape beat; breath-holding caused sinus brandycardia with A-V block and nodal escape associated with drop in blood pressure and syncope; thereafter every breath-holding episode could cause change in pacemaker to atrial focus; after atropinization dissociation and changes in pacemaker noted; after adequate time for complete atropinization, patient entered normal sinus rhythm which persisted despite breathing maneuvers.
27	22	None	Breath-holding resulted in shift in pacemaker to secondary atrial focus; after atropinization, breath-holding produced no changes from normal sinus rhythm
28	21	None	During breath-holding patient developed A-V dissociation, felt weak, but recovered; after atropinization, breath-holding produced no changes from normal sinus rhythm
29	21	None	No findings
30	26	None	Breath-holding resulted in shift in pacemaker to secondary site in atria; after atropinization, shifts could not be induced
31	20	None	Breath-holding was associated with cardiac slowing and in recovery period A-V dissociation and nodal rhythm occurred, cardiac rate dropping to 44/min.; syncope resulted; patient rested in recumbent position, was then tilted to the vertical position, resulting in progressive cardiac slowing, short period of asystole followed by nodal escape, and syncope; atropinization not followed sufficiently long for evaluation of atropine effect
32	21	None	No findings
33	21	None	Breath-holding resulted in cardiac slowing, A-V dissociation, nodal rhythm; breath-holding after hyperventilation resulted in lower nodal rhythm, A-V dissociation; after atropinization, breath-holding produced no changes from normal sinus rhythm
34	21	At ages 16 and 17, patient had episodes of syncope after long periods of reading or watching television	Breath-holding after hyperventilation resulted in shift in pacemaker to secondary atrial focus, also noted with breath-holding without hyperventilation; after atropinization, breath-holding produced no changes from normal sinus rhythm
35	21	None	At onset of base-line studies with patient first assuming position on tilt-table, there was shift in pacemaker to nodal rhythm followed by a 5-sec. period of asystole and syncope; after recovery period, breath-holding would produce A-V dissociation and nodal rhythm; near syncope occurred during recovery period after breath-holding; after atropinization, normal sinus rhythm developed and no further arrhythmias or syncope could be induced
36	22	None	1 min. after right carotid sinus massage, sinus bradycardia followed by shift in pacemaker to atrial, then nodal, focus, associated with near syncopal episode; after recovery, breath-holding alone was associated with marked cardiac slowing and near syncope; after atropinization, breath-holding produced no changes from normal sinus rhythm
37	22	None	No findings
38	23	None	After right carotid sinus massage, marked decrease in blood pressure with sinus bradycardia (rate 47/min.) and syncope
39	21	Syncope occurred while donating blood	Breath-holding resulted in cardiac slowing with shift in pacemaker to secondary atrial site; during prolonged breath-holding, there was a 2-sec. period of asystole associated with marked decrease in blood pressure and near syncope; after atropinization, breath-holding produced no changes from normal sinus rhythm
40	20	Syncope occurred following injection of procaine	Breath-holding resulted in two atrial premature contractions; breath-holding after hyperventilation resulted in A-V dissociation, nodal rhythm, and occasional atrial premature contractions; after atropinization, breath-holding produced no changes from normal sinus rhythm
41	27	Syncope induced by blowing against thumb after period of hyperventilation	Breath-holding resulted in A-V dissociation with nodal rhythm; breath-holding after hyperventilation again resulted in A-V dissociation with nodal rhythm; upon expiration, nodal tachycardia ensued associated with near syncopal episode; after atropinization, breath-holding produced no changes from normal sinus rhythm
42	22	None	Breath-holding resulted in shift in pacemaker to secondary atrial focus; after atropinization, breath-holding produced no changes from normal sinus rhythm
43	20	None	Breath-holding resulted in A-V dissociation and nodal rhythm; after atropinization, breath-holding produced no changes from normal sinus rhythm
44	20	None	Left carotid sinus massage resulted in cardiac slowing with shift in pacemaker to secondary focus, atrial rhythm, nodal beat, and asystole followed by syncope; thereafter repeated episodes of breath-holding resulted in shift of pacemaker to secondary atrial focus with atrial rhythm, A-V dissociation, and nodal rhythm; after atropinization, breath-holding produced no changes from normal sinus rhythm
45	21	None	Two minutes after right carotid sinus massage, first-degree A-V block occurred followed by second-degree A-V block, with an 8-sec. period of no ventricular response followed by syncope
46	20	Self-initiated syncope	On every occasion immediately after release of breath, patient developed A-V dissociation with block; this did not recur after administration of atropine
47	19	Syncope at age 14 while laceration was being sutured and, on another occasion, after venipuncture	At onset of base-line studies when patient first assumed position on tilt-table, A-V dissociation with nodal rhythm occurred followed by syncope; 41 sec. after right carotid sinus massage, period of asystole followed by syncope; breath-holding was not done in this person
48	21	None	Breath-holding resulted in shift of pacemaker to secondary atrial focus; 30 sec. after left carotid sinus massage, marked cardiac slowing with nodal rhythm and syncope; thereafter breath-holding produced nodal rhythm with syncope; after atropinization, breath-holding produced no changes from normal sinus rhythm
49	21	None	No findings
50	19	Syncope while running 2-mile race at 1.75-mile mark	No findings

---

* Frequent arrhythmias (e. g., A-V dissociation) were noted immediately after injection of atropine due to initial atropine effect. All maneuvers to test full atropinization were performed at 6 min. or more after intravenous administration to avoid confusion of early transitory effects of atropine with the syncope procedures.

made to identify the number with the subject's name. He was then asked to report whether he had truly had any syncopal episodes in the past and what the circumstances surrounding these were. The purpose of this was to detect, if possible, an index of the number of individuals entering a flying training program who intentionally suppressed information relative to previous syncopal episodes in order to be accepted in the program.

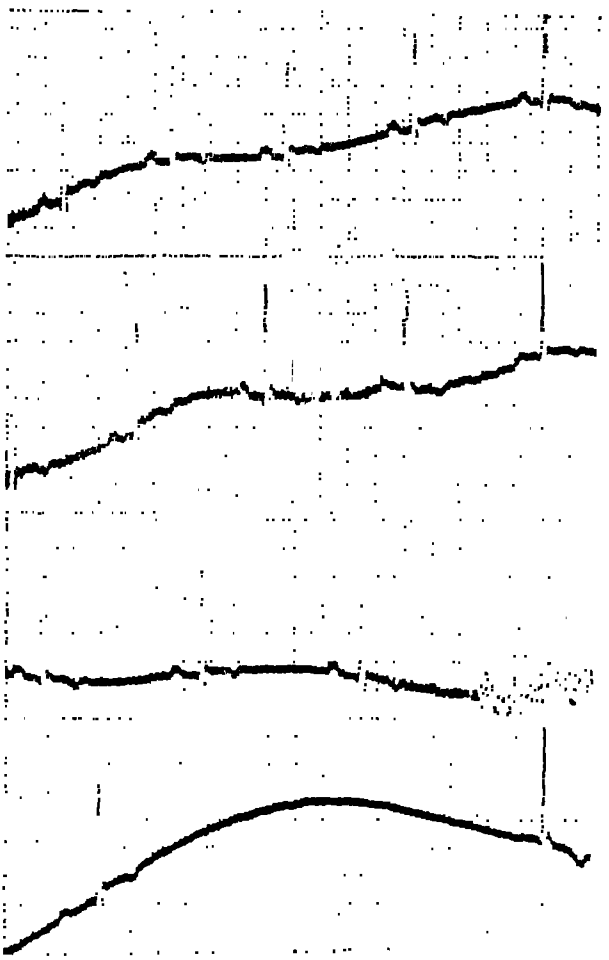

Fig. 1 (case 31).—Continuous lead 2 shows progressive slowing, with eventual sinus arrest and nodal escape. This was result of orthostatic influences.

Results

One of the most interesting facets of this study was learning the true incidence of syncope in such a group. Of the 50 aviation cadets, 15 (30%) admitted to previous undisclosed syncope.

During the experimental procedures, 21 (42%) of the subjects had one or more syncopal episodes, or near enough to syncope to stop the precipitating cause. Of the group having experimental syncope, 15 (71%) had significant cardiac arrhythmias associated with the syncopal episode. Two of the subjects having cardiac arrhythmias associated with syncope also had significant drop in blood pressure at the onset of the arrhythmia. In seven subjects, breath-holding produced syncope with arrhythmia. One subject had syncope with arrhythmia secondary to breath-holding after hyperventilation. In five subjects, carotid sinus stimulation produced arrhythmia associated with syncope. Five of the 15 subjects had syncope associated with arrhythmia due to orthostatic influences. This represented all cases of syncope due to orthostatic influences. The apparent discrepancy in numbers is due to the fact that a few subjects had syncope from more than one precipitating factor.

Syncope may occur with breathing maneuvers in the absence of apparent significant cardiac arrhythmia. There were 11 subjects (22%) in all who had syncope with breath-holding maneuvers and an additional subject who had syncope with breath-holding after hyperventilation. Often the syncopal episode occurred during the recovery phase after breath-holding. The true incidence of syncopal episodes which might be precipitated by such breathing maneuvers is slightly higher than this, as those individuals who had strong orthostatic influences were not always subjected to the remainder of the experimental protocol. This decision was made since these individuals could not be properly evaluated concerning their response to specific stimuli. In 9 of the 21 subjects, syncope could be induced with carotid sinus massage (five associated with cardiac arrhythmia and four without arrhythmia). Syncope commonly occurred after rather than during massage. In five of the subjects syncope could be induced by orthostatic influences (all five were associated with arrhythmia).

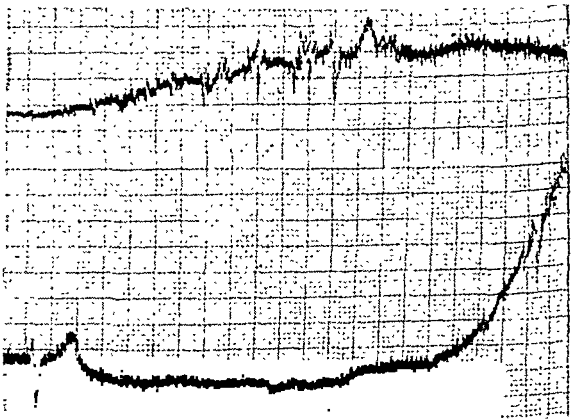

Fig. 2 (case 5).—Continuous lead 3 taken within three minutes after patient had been standing on tilt-table (upright 90 degrees). Sinus arrest with escape beats occurred and syncope followed. Artifact of muscle tremor is present. Subject was tilted to recumbent position and recovered.

Of the 15 cadets who admitted to previous syncopal episodes that had not been previously disclosed, 7 developed experimental syncope during the procedure. This, of course, means that eight other subjects who had previous clinical syncope had no syncopal episodes during the experimental procedures. Fourteen subjects who experienced syncope under experimental conditions denied any previous episode of clinical syncope.

In all the examples of syncope in this series, none were induced by breath-holding at the height of inspiration. All syncopal episodes secondary to breathing maneuvers were due to prolonged breath-holding and/or breath-holding after a period of hyperventilation. Breath-holding after hyperventilation commonly produced effects similar to prolonged breath-holding. Therefore, it is listed in a separate category only when it alone, as an additional stress mechanism, induced a syncopal episode.

Of the 50 subjects undergoing the experimental syncope procedures, 37 (74%) demonstrated some form of cardiac arrhythmia. In 22 instances, the cardiac arrhythmia occurred without subsequent syncope. More than one form of stress was capable of producing arrhythmia in a number of the individuals. In 26 subjects (52%), cardiac arrhythmia of some type could be induced by breath-holding and by breath-holding after hyperventilation. In two additional cases, cardiac arrhythmia was induced only by breath-holding after hyperventilation. Twenty-eight (56%) of the cadets had some form of cardiac arrhythmia after one of the respiratory maneuvers. Eight cadets (16%) demonstrated cardiac arrhythmias after carotid sinus massage. Five cadets (10%) developed cardiac arrhythmia associated with orthostatic stress. It is interesting to note that of the seven subjects who had a previous clinical episode of syncope as well as having syncope during he experimental routine, six had syncope secondary to breath-holding and one due to orthostatic influences.

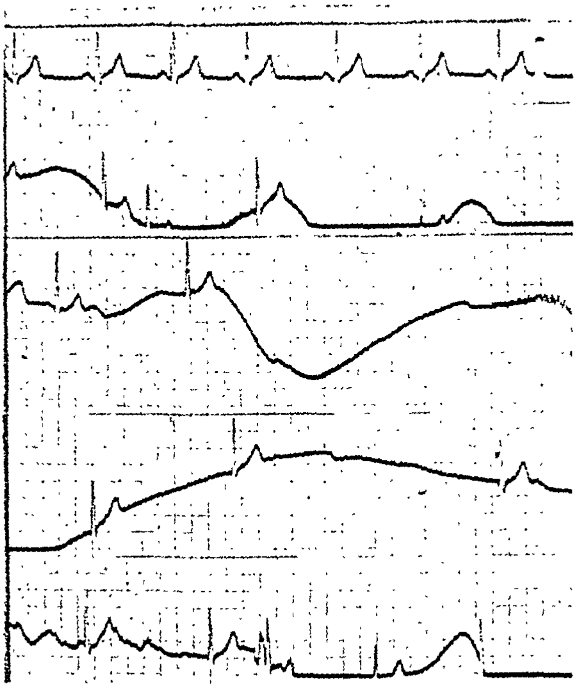

Fig. 3 (case 35).—Top strip demonstrates base-line lead 2 for patient in recumbent position. Remaining tracing is continuous lead 2 taken within three minutes after patient had been tilted to upright (90-degree) position. *Sinus arrest* with nodal escape and slow nodal rhythm is demonstrated. This occurred at onset of base-line studies to begin procedures.

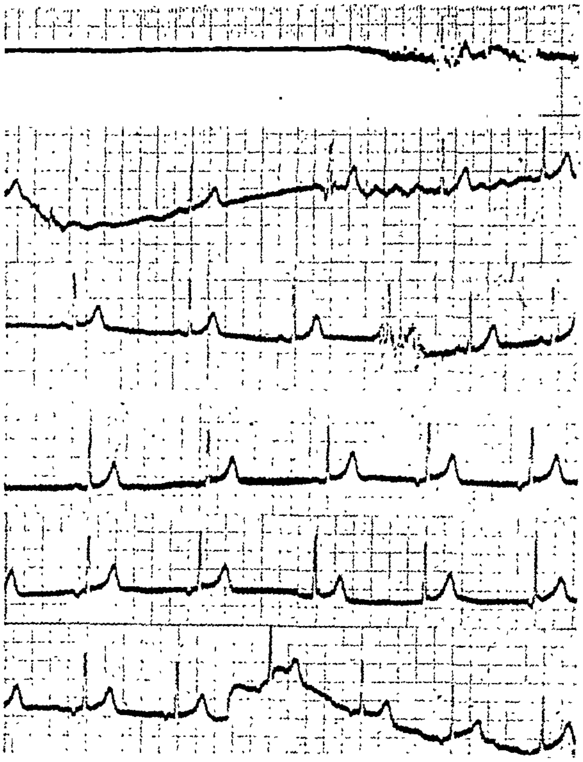

Fig. 4 (case 6).—*Above*, continuous lead 2 demonstrates period of cardiac arrest terminated by escape beats and transitory atrial flutter. This episode occurred two minutes after carotid sinus massage with patient standing (90 degrees) on tilt-table. *Below*, continuous lead 2 after tilting of patient to the horizontal position demonstrates atrial rhythm. Second strip shows atrial rhythm with A-V dissociation. Note inverted P wave just emerging before the last QRS event.

In 30 instances in which a cardiac arrhythmia was induced by respiratory maneuvers, atropine was administered. After adequate atropinization (approximately six minutes after the injection of 1/50 grain of atropine), in no instance were any cardiac arrhythmias induced by any of the respiratory maneuvers.

A very brief summary of the findings in the individual cases is presented in the table.

Comment

The incidence of syncope in this group of cadets beginning flying training suggests that the reported low incidence of syncope in cadets is entirely fictitious and represents a suppression of information by the cadet applicants in order to gain entrance into the program. If a similarly high incidence of syncope should exist in all of the individuals accepted for preflight training, it may be assumed that between 18 and 42% of all pilots beginning flying training have already experienced some form of clinical syncope. (The observed proportion of 30% is a sample estimate of the true proportion in the total population of pilots beginning flying training. As such, it is subject to sampling variation. Using a confidence interval of 2σ, it can be expected that there is only 1 chance in 20 that the true proportion having an episode of syncope lies below 18 or above 42%.) Needless to say, a large percentage of these individuals complete their flying training and carry out to completion a useful flying career.

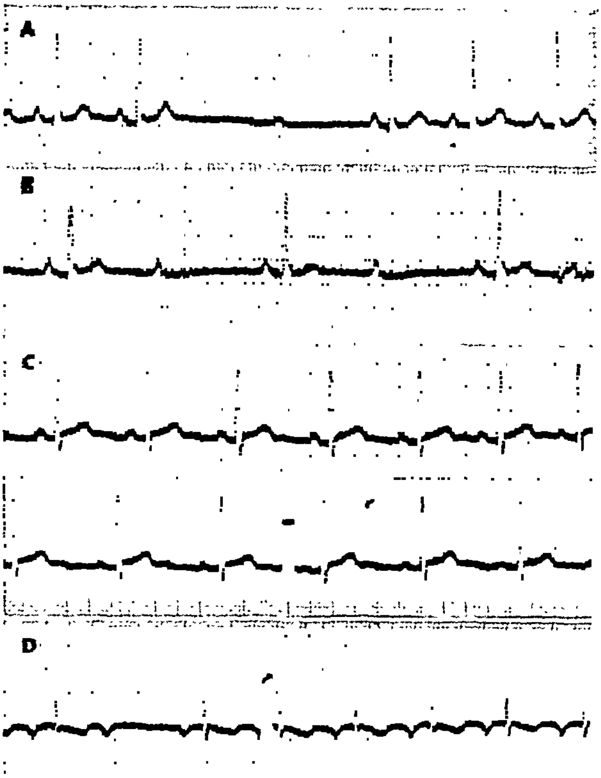

Fig. 5.—*A* (case 9), A-V block occurs just at the height of inspiration and onset of breath-holding. *B* (case 9), more persistent second-degree A-V block during prolonged breath-holding. *C* (case 10), continuous lead 2 demonstrates change in pacemaker occurring with breath-holding. *D* (case 3), lead 3 demonstrates atrial rhythm and A-V block precipitated by breath-holding after hyperventilation.

Syncope as Underlying Disease State. The relatively high incidence of syncope in a normal aviation cadet preflight group is strong argument against the concept that syncope itself presents an underlying disease state. It is difficult to assume that 30% of our highly selected, apparently healthy young men have an underlying disease process or disease complex which causes them to be subsequent hazards to flying or other crucial industrial situations.

Cardiac Arrhythmias.—In this series, it was impressive to note the high incidence of cardiac arrhythmias associated with syncopal episodes. Cardiac arrhythmias appeared to be important even in the presence of experimental orthostatic syncope. While it was previously noted [1a] that cardiac arrhythmias were important in syncope induced by respiratory maneuvers, this finding in orthostatic syncope suggests their importance in other forms of syncope as well (fig. 1, 2, and 3). Subjects 5, 17, 31, 35, and 47 demonstrated significant cardiac arrhythmia in association with their syncopal episodes.

Carotid sinus massage induced syncope, commonly presenting both cardiac arrhythmia and vasodepressor response (fig. 4). The respiratory maneuvers presented the largest number and the largest variety of cardiac arrhythmias. Passive rhythms, including atrial rhythm, A-V dissociation with nodal rhythm, and lower nodal rhythm were commonly noted (fig. 5, 6, and 7). One episode of nodal tachycardia was also observed (fig. 8).

In some instances cardiac arrhythmias were distinctly obvious as the major factor precipitating a syncopal episode. In the presence of cardiac arrest with no cardiac beat, no alternative explanation seems feasible. In those cardiac arrhythmias which resulted in marked depression of the cardiac rate, it might be assumed that the accompanying cardiac arrhythmia in the presence of other factors was sufficient to create syncope. In the event that any degree of vasodepressor syncope is present with peripheral arteriolar dilatation, progressive depression of the cardiac rate further compromises cardiac output. This in turn can be expected to lead to cerebral ischemia and present as a syncopal episode. As indicated in a previous paper,[2] the respiratory reflexes which originate from stretch receptors within the lungs stimulate the same efferent reflex pathways that are stimulated by the carotid sinus afferent nerves. Thus, one should expect both vasodepressor and cardiac arrhythmia responses when the respiratory stretch reflex is stimulated. In this series, the cardiac arrhythmias seem to be a major factor.

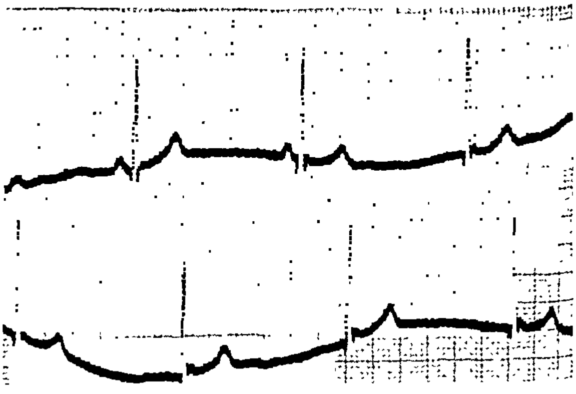

Fig. 6 (case 19).—Continuous lead 2 demonstrates onset of nodal rhythm with breath-holding.

Effect of Atropine Administration: Another interesting finding was that cardiac arrhythmias were not induced in any case by respiratory maneuvers after the administration of atropine. This strongly suggests that adequate atropinization provides a protective mechanism against developing cardiac arrhythmias by stress procedures. It follows that previous experimentation [3] which has utilized orthostatic tests with the concomitant administration of atropine has protected the experimental subject from demonstrating cardiac arrhythmias. It seems that not only may atropine act to produce syncope by creating visceral pooling but also it may prevent syncope by abolishing vagal reflexes which cause cardiac inhibition and result in cardiac arrhythmia. Impending syncopal episodes were prevented on several occasions in subjects of this series by the intravenous administration of atropine.

Changes in Electrolyte Pattern: One might ask what role shifts in electrolytes might play in the cardiac arrhythmias precipitated by respiratory maneuvers. It is pertinent to point out that cardiac arrhythmias were induced in subjects by prolonged breath-holding and also by breath-holding at the height of inspiration after hyperventilation. In the former instance with prolonged breath-holding, carbon dioxide retention should result in a tendency toward respiratory acidosis. In the latter instance, hyperventilation should tend toward respiratory alkalosis. Regardless of these two extremes in the assumed change in electrolyte pattern, cardiac arrhythmia was induced.

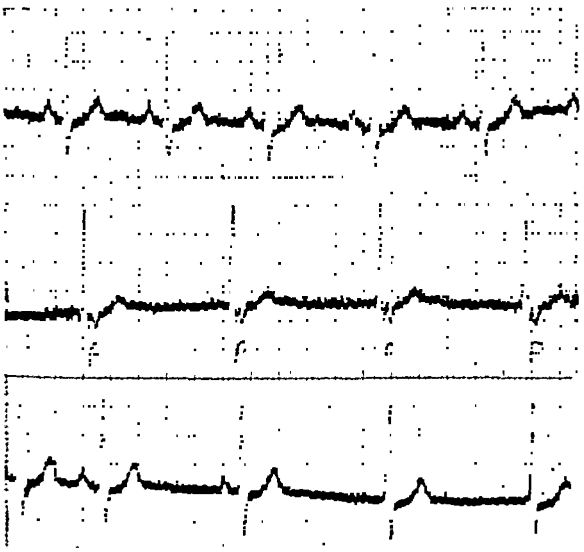

Fig. 7 (case 33).—Continuous lead 2 demonstrates lower nodal rhythm induced by breath-holding after hyperventilation.

A point of some interest in this series was the absence of syncope occurring immediately with breath-holding at the height of inspiration. Two subjects in the previous reported series of syncope patients [2] did present this finding.

Effect of Age: This particular group of subjects is not entirely comparable to those previously studied as they obviously represent a somewhat younger age group. It is well known that differences in vagotonia occur with different age groups. Marked sinus arrhythmia is more prone to occur in the younger individual. Whether this is a significant difference in the two groups studied to date is not known.

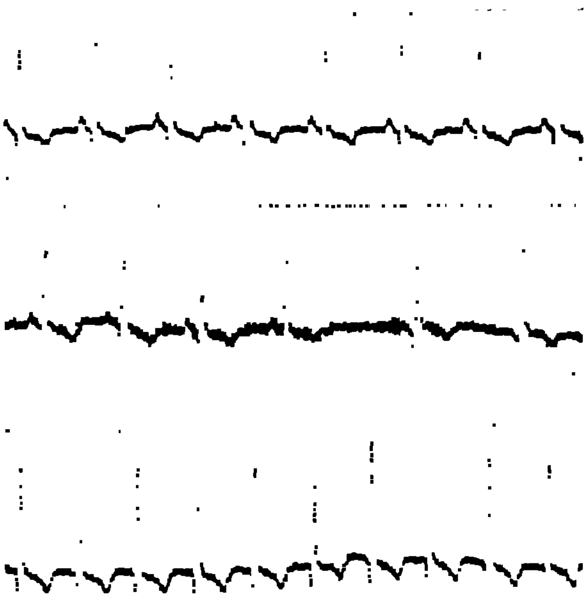

Fig. 8 (case 41).—Lead 2 demonstrates nodal rhythm and burst of nodal tachycardia induced by breath-holding after hyperventilation.

It is apparent from the study of this small group of aviation cadets that the incidence of clinical syncope in cadet applicants is considerably higher than has been previously supposed. Much needs to be done before any statement can be made concerning selection techniques to predict the future occurrence of syncope in any individual. It is highly significant that 14 individuals who presented experimental syncope by currently used procedures had apparently never experienced syncope on any other occasion. On the other hand, the experimental procedures were not able to identify the subjects who had previously experienced syncope. An individual may be syncope prone at one period of his life due to temporary circumstances (e. g., recent excessive rapid weight loss) and not be syncope prone on subsequent occasions.

Summary

Fifty young, apparently healthy aviation cadets in preflight training were evaluated in regard to syncope. Thirty per cent of these subjects admitted to previous, undisclosed syncope when they were not in fear of detection or removal from the training program. Twenty-one of the cadets experienced experimental syncope during the syncope proce-

dures. Cardiac arrhythmia was frequently associated with the syncopal episode and cardiac arrhythmia was frequently induced by respiratory maneuvers without syncope. Intravenously given atropine apparently prevented recurrence of cardiac arrhythmia induced by respiratory maneuvers. Significant cardiac arrhythmia was also noted in simple orthostatic syncope.

EXPERIENCE WITH MEDICARE

Paul I. Robinson, M.D., New York

Wives, children, and dependent husbands of active duty personnel of the seven uniformed services have been receiving care from civilian physicians in civilian hospitals under the Medicare program. An analysis of results after 18 months of operation indicates the value of this program. Sample studies show that 41.4% of the care rendered has been obstetrical and that initiation of the program was followed by a marked drop of deliveries in uniformed services facilities and a marked increase of deliveries in the civilian facilities. A comparison of average daily patient loads showed that an average of 54% more dependents a day received medical care at government expense in 1957 (under the Medicare program) than in 1956 but that the number receiving such care in uniformed services facilities decreased by 11.6%. Additional evidence that Medicare is acceptable to uniformed personnel was obtained by questionnaire. Allegations that it had inflationary effects and influenced physicians to overcharge lack cogent proof, and it is believed, rather, that physicians themselves can control those few who charge unreasonably. The program has brought medical care to many people who apparently would not have gone to the hospitals of the uniformed services. It represents a challenge to the facilities of the uniformed services to adjust their methods of affording medical care to dependents, but it also represents a challenge to local medical associations in the areas of schedules of allowances and their utilization.

Last year at this time, it was only possible to report that the Dependents' Medical Care Program (Medicare), for wives and children and dependent husbands of active duty personnel of the uniformed services, had been placed in being. The program had been in effect barely six months. Now, dependents have been receiving care from civilian physicians in civilian hospitals for 18 months. By March, 1958, $35,957,020 had been paid to physicians and $35,154,621 to hospitals, and these amounts were reimbursed to Blue Cross, Blue Shield, state medical associations, and insurance companies who are acting as fiscal administrators under contract. These remarks are directed toward analysis of two phases of this program: (1) what it is doing for the uniformed services and (2) what it is doing for the profession of medicine.

As of March 1, 1958, physicians of all states, the District of Columbia, the territories of Hawaii and Alaska, and the Commonwealth of Puerto Rico participated in the program. Four states reported 34.8% of all physicians' claims; California, reporting 79,831 (18.2%) physicians' claims, led, and Texas followed with 35,700 (8.1%). Next were Virginia, reporting 19,876 (4.5%), and Florida, with 17,572 (4.0%). North Dakota had the fewest claims and Alaska next fewest. By geographical area, the Pacific states led with 21.9% and next came the South Atlantic states with 21.6%. The New England states had the fewest (5.5%). Sample studies in several states indicate that from 30% to 40% of registered physicians have cared for one or more patients. These same studies indicate that 77.3% of the participating physicians had been paid less than $500 each, and only 0.2% had received $10,000 or more. It is evident that the patients

Coordinator, Medical Relations, Metropolitan Life Insurance Company. Formerly Executive Director, Office for Dependents' Medical Care, Office of the Surgeon General, U. S. Army, Washington D. C.

Read before the Section on Military Medicine at the 107th Annual Meeting of the American Medical Association, San Francisco, June 27, 1958.

are being cared for in greatest numbers in those states with the largest troop concentrations. As far as the profession is concerned, the program is a small one but it is extremely widespread in its application because personnel of the uniformed services reside in every hamlet of the United States and their dependents many times return to their homes when they are unable to accompany their sponsors. This is well illustrated by the fact that 88% of all of the dependents cared for in West Virginia were residing apart from their sponsors and 43% of all patients in the program were residing apart from their sponsors because of the exigencies of the uniformed service.

Effect on Physicians' Fees

At the inception of the program, the Office for Dependents' Medical Care depended a great deal on the experience and wisdom of the state medical associations in many aspects of the program. Notable in this regard was the determination as to whether or not the schedules of allowances would or would not be published to the physicians of the state. There was, and still is, a great difference in philosophy of state medical associations as to physicians charges. Some, our experience would indicate, believe that physicians should be entitled to a fixed fee, regardless of type of practice or state of training. These states published their schedules of allowances, and, with few exceptions, physicians charges conform therewith. Others were of the opinion that every physician should know the maximum negotiated allowance but that he should charge his usual fee. These states also published their schedules but encouraged physicians to charge their usual charges. Our experience in these areas indicates that there are a considerable number of physicians who do charge below the maximum of the schedule but by far the greater majority charge the amount published in the schedule. A third group of states feels that physicians should determine their charges in each individual case, considering all factors. They have not published their schedules but have assured their physicians that a fair and equitable amount has been negotiated and have instructed them to charge an amount equal to their ordinary charge for patients in like circumstances. Our experience in this group of states indicates that the physicians charges conform, in general, to normal civilian practice, a considerably greater number being below the modal amount and a few being higher than the schedule.

It is not considered to be within the scope of the Office for Dependents' Medical Care to express an opinion on this great problem of physicians' remuneration. We are aware of the allegations that insurance, Blue Shield, and other similar programs are having inflationary effects and influence physicians to "overcharge." Our experience does not dictate that we subscribe to this allegation. We believe that the vast majority of physicians' charges in our program are reasonable and not seriously out of line with those in civilian life. We believe that physicians themselves can control those few who charge unreasonably, and we have in our files many examples of just such actions on the part of Medicare committees within the states. The physicians of the nation have a challenge in this program in that they have a distinct opportunity to control many features of its operation.

Type of Care Rendered

Sample studies have indicated that 41.4% of the care rendered in the program is for obstetric service. While the figures are not exactly comparable because of different definitions of stillbirths used in uniformed services facilities and in some of the states in civilian life, it is appropriate that this field be discussed. In 1956 (January through August), there were 114,129 deliveries in uniformed services hospitals in the United States, Alaska, Hawaii, and Puerto Rico; in the same months for 1957, there were 82,805 births in these facilities. In civilian facilities, under the Dependents' Medical Care Program during the same period of time (1957), there were approximately 77,910 deliveries.

In other words, there had been a reduction in uniformed services facilities of 31,324 deliveries in the same period from 1956 to 1957. If the civilian program was responsible for all of this reduction, it had also taken care of 46,586 additional deliveries. It was impossible to extend this study further into 1957 and 1958 because of incomplete information in the Dependents' Medical Care Program. If this had been possible, it is likely that a still greater drop of deliveries in uniformed services facilities would have been noted and an increase in the civilian program. This is understandable. Expectant mothers desire personal attention by one physician, they like privacy, they like to discuss the type of anesthesia they will be given, and they dislike long waiting periods. They feel they have a better chance of getting all of this in the civilian program, and the uniformed services may have to make some changes in many of their installations if they desire to continue active and large obstetric services.

On the basis of an average daily patient load study made in the same comparative period (January through August, 1956-1957), while obstetric and gynecologic care given in uniformed services facilities dropped 19.7%, all other care for dependents dropped only 5.8%. It is known that there was a considerable backlog of tonsillectomies in many uniformed services clinics and that scores of these operations were accomplished in the early months of the civilian program. There has been a reduction of approximately 2% in troop strength. Certain uniformed services facilities are not staffed and equipped to accomplish all procedures of a medical nature. In view of these considerations, the drop of 5.8% in all care except that in obstetrics and gynecology may not be more than expected or desired by the uniformed services.

Choice of Government and Civilian Facilities

Since the hearings before the Appropriations Committee of the House of Representatives in April, 1957, there has been considerable discussion in the Defense Department and in civilian medical and hospital forums of the policy of permitting the patient to have "free choice" between uniformed service and civilian facilities and physicians. You are aware of the fact that the law affords an opportunity for restriction of those dependents who reside with their sponsors (approximately 57% of dependents who have participated in the program). Sincere attempts have been made to compare costs of medical care in uniformed services facilities with those in civilian communities. At this time, no valid comparison has been made. It is our opinion that much more detailed studies will have to be conducted before any conclusions can be drawn. There are many other factors which must be given thought when restrictions of "free choice" are considered.

Hospital admissions are cheaper to the dependent in uniformed service facilities, because for civilian care they must pay $25 for any period in the hospital of 14 days or less whereas in uniformed services hospitals they pay only $1.75 per day.

A small number of state medical associations sincerely feel that the Dependents' Medical Care Program should be operated on an indemnity basis. A great many more, however, are just as sincere in their beliefs that the program would not be successful if operated on an indemnity basis. The administration of the program, part indemnity and part full coverage, insofar as physicians' service is concerned would be most difficult, if not impossible. To the services this would mean that physicians in the indemnity states could charge patients additionally whereas in other states they could not. Insofar as hospitalized dependents are concerned, physicians' charges are on a full service basis. But hospital charges are on a deductible basis, as are physicians' charges for authorized outpatient care. The Medicare plan is an individual plan designed to furnish medical care specifically to dependents of uniformed services personnel. Continued efforts are being made to acquaint everyone with the plan in its proper perspective. This difference of opinion among state medical associations as to the type of program is perhaps a reflection of a continuing issue in the acceptance of voluntary health insurance. A change in the method of operation of the Dependents' Medical Care Program would probably have very little influence on the ultimate solution of the problems in the health planning field which confront physicians of the nation, the health insurance industry, and the government.

The average daily patient load of dependents in uniformed services facilities in the United States, Alaska, Hawaii, and Puerto Rico during the period of January through August, 1956, was 6,876, whereas in the same period of 1957 it was 6,075, a decrease of 11.6%. In the same period and area the average daily patient load in civilian facilities under the Dependents' Medical Care Program was 4,531. In both uniformed service and civilian facilities, an average of 10,606 dependents each day received medical care in 1957, as against 6,876 in 1956. In other words, an average of 54.2% more dependents a day received medical care at government expense in 1957 than in 1956.

Since September, 1957, 750 questionnaires have been sent to sponsors whose dependents have received care in civilian facilities under the program. In answer to a question as to why they chose to use the civilian program rather than a uniformed service facility, 43.6% said they resided too far from a uniformed service hospital; 14.9% stated that the type of care required was not available at uniformed service hospital; 13.8% preferred civilian facilities for diverse reasons; 12.8% said the uniformed service hospital was inadequate or overcrowded; 7.0% preferred the services of a particular physician or hospital; 5.0% received emergency care; and 2.9% stated the civilian facility was more convenient.

In an open section for general comments on the program, 25% gave gratuitous praise to the program, 48% had no comment, and the remaining 27% commented that they thought the program should be extended to include outpatient care, dental care, drugs, and other items or made comments on costs to them being rather high or information being difficult to find. In general, the replies to these questionnaires lead us to believe that the program has a high degree of acceptance among uniformed services personnel.

Summary and Conclusions

Evidence is available substantiating the belief that the Dependents' Medical Care Program is rendering medical care to those who could not reasonably obtain this service in hospitals of the uniformed services. In general, the program has had excellent reception by the physicians of the United States. However, it presents a distinct challenge to local medical associations in their own operational responsibilities in the areas of schedules of allowances and their utilization. It also presents a real challenge to the uniformed services medical facilities in improving care for dependent patients. The Office for Dependents' Medical Care desires to recognize the invaluable assistance which has been given to it over the past year by the surgeons general of the U. S. Army, Navy, Air Force, and Public Health Service, by the advisory committees of the American Medical Association, the American Hospital Association, and the Secretary of Defense, and by the state medical associations and their fiscal administrators, who have always been considerate and helpful in arriving at solutions to perplexing problems. The personal interest and unfailing support of the Secretary of the Army, as executive agent for the program, has been one of the great contributing factors to the success of the program during these trial months. The Office for Dependents' Medical Care will continue to try to administer the program with the interests of all the uniformed services and all the physicians and hospitals of the nation in mind in an endeavor to render medical service to dependents of the active members of the seven uniformed services in conformance with the desires of Congress.

⁂

HEMATURIA IN BOXERS

Aaron H. Kleiman, M.D., New York

Disturbances of renal and vesical function were studied in 764 professional boxers participating in 150 events during a three-year period. A urologic history was obtained from each subject, and altogether 2,200 specimens of urine were obtained before bouts for comparison with specimens obtained after bouts. Comparisons were also possible between 132 substitutes who were prepared to box but not called upon to do so and pugilists who did box. Only 1,518 urine specimens were obtained immediately after bouts because 550 boxers were unable to urinate for several hours after the bout. Significant hematuria (6 or more red blood cells per high-power field) was found in 415 (27% of 1,518) postbout specimens of urine; 30 specimens were salmon pink, 8 were bright red, and 4 were dark red. A significant number of boxers showed consistently normal urinalyses even after four or more bouts. Roentgenographic studies revealed structural adnormalities of the kidneys in many cases of hematuria and suggested that such defects render the kidneys more susceptible to the trauma of boxing as demonstrated by the high incidence of recurrent prebout hematuria.

Significant hematuria, defined in this study as six or more red blood cells per high-power field, is generally regarded as a serious symptom for which a complete urologic investigation is indicated. Little mention is made in the literature, however, of such surveys in groups of athletes. After exercise or training, blood is commonly found in the urine of athletes engaged in all contact sports, including boxing.[1] In such men exercise may be considered as a provocative test demonstrating hematuria which may not be present at rest. Such hematuria, while usually innocent, transient, and painless, may also be indicative of prodromal states in the kidney which require careful investigation and treatment.

The present report is based on a three-year urologic study of 764 professional boxers participating in 150 events at Madison Square Garden and St. Nicholas Arena in New York. A series of investigations was conducted which demonstrated a correlation between boxing hematuria and morphologic and physiological changes in the upper urinary tract. These observations suggest that boxing hematuria is usually of traumatic and mechanical origin. It is hoped that these studies will help to supplement existing knowledge concerning the nature of renal trauma.

Methods

The investigation included (1) clinical and laboratory examinations during the day of the bout, (2) observations of boxers in the ring, (3) roentgenographic examinations of the urinary tract in 100 boxers with significant hematuria, and (4) supplemental clinical studies of boxers, other athletes, and groups of nonathletes for control observations.

Clinical Examination During Day of Bout.—The mid-day examination was conducted in the medical offices of the New York State Athletic Commission prior to the weighing-in of the pugilists. Complete physical examinations were made by Drs. Alexander Schiff, Vincent Nardiello, and Samuel Swetnick. I obtained a urologic history from each subject and collected samples of urine by the two-glass method. Urinalyses were then performed, and clinical and laboratory data were recorded. In all, 2,200 prebout urine specimens were collected.

Before his scheduled bout, I reexamined each boxer in the dressing room. Temperature, blood pressure, pulse rate, and respiration rate were noted

for comparison with earlier and later records. From 12 to 16 pugilists were examined for each ring event, and all but a few of these actually boxed. The others were substitute boxers (emergency bouts) who remained available in case of the early knockout of a featured boxer. There were 132 such men examined.

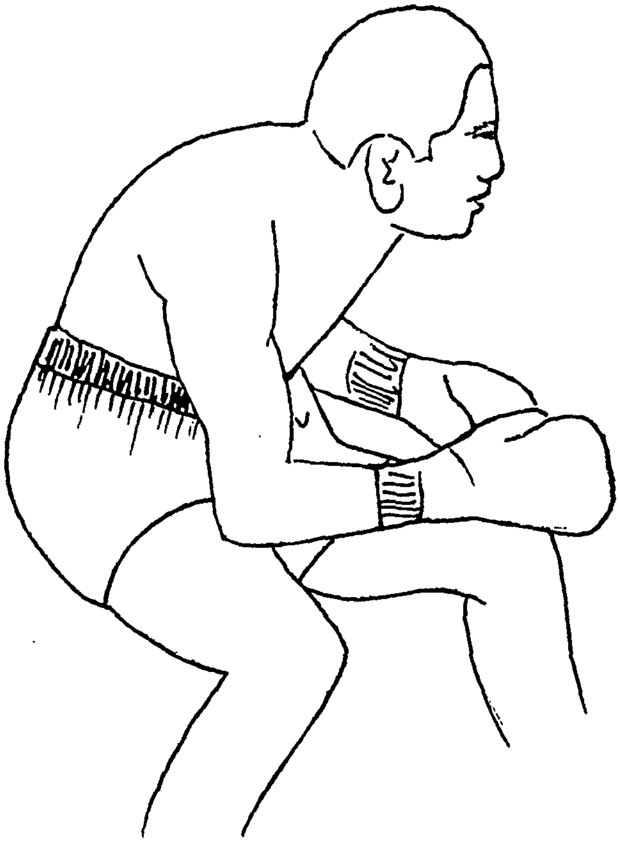

Fig. 1.—Boxer in crouch position. Repeated trauma is received in arched position. Action of diaphragm and abdominal muscles plays role in renal trauma and ptosis.

Immediately after participating in a contest, each pugilist was given a special urologic examination. Emphasis was placed on areas of tenderness over the loin or abdomen. Blood pressure, pulse rate, temperature, and respiration rate were again recorded. Whenever possible, the urine was collected by the two-glass method. Since 550 boxers were unable to void for several hours after the bout, and the 132 substitutes did not box, only 1,518 postbout urine specimens were available for analysis.

Ring Observations.—The boxing performances of most of the subjects under study were witnessed personally. Thus, evaluation of boxing styles, "kidney punches," knockdowns, and lacerations about the face and head was possible.

The typical boxer assumes a modified crouch position when facing his opponent (fig. 1). For better balance in the ring, his left foot is placed about 15 in. in front of his right and at a 90-degree angle. His extended left upper extremity is used for offensive tactics and his flexed right upper extremity for defense against blows to the face or body. At precise opportune intervals, the stronger right fist is used to deliver the most damaging blows.

During an attack, many boxers emit a loud grunt which is timed with the delivery of a punch ("grunt reflex"). This grunt is produced by combined action of the diaphragm and abdominal muscles, and it causes the diaphragm to contract against the kidney with possible renal displacement as a consequence. Both the grunt reflex and blows received directly to the abdomen in the semicrouched position are prominent etiological factors in hematuria, renal trauma, and excessive renal mobility. Such blows to the abdominal and kidney regions are far fewer than those directed to the head and face, which comprise about 85% of all blows delivered in the average contest. Many abdominal punches are blocked or slipped. Loin blows are usually received by the left kidney (fig. 2), but since these are indirect their force is attenuated. The left renal trauma is usually not as pronounced as when a blow is delivered directly to the right upper quadrant of the abdomen, with right renal injury more frequent as a consequence (fig. 3).

Roentgenographic Studies.—Intravenous urography was performed in 100 volunteers out of 415 men found to have significant boxing hematuria. The studies were made at the medical offices of the New York State Athletic Commission within three days after a bout. Findings on urinalyses were usually normal at this time.

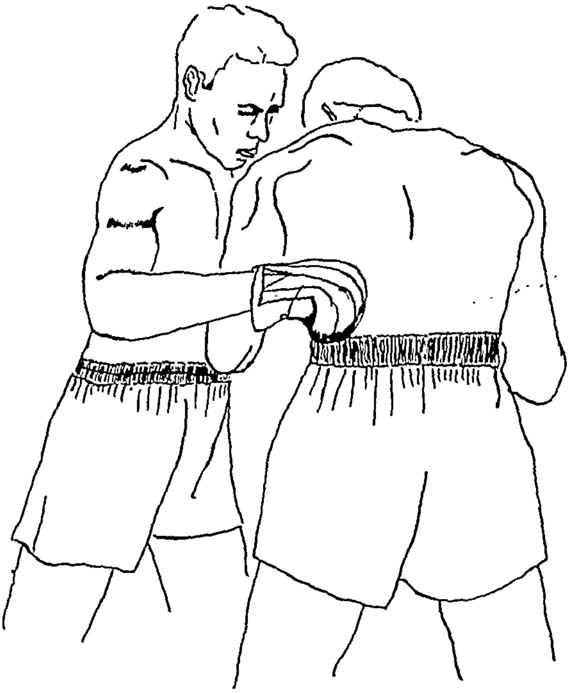

Fig. 2.—Loin blow received by left kidney. Such blows are less traumatic than direct blows to right upper abdominal quadrant.

After a preliminary scout-film study, 20 cc. of diatrizoate (Hypaque) sodium was slowly injected into a vein of the forearm. Roentgenographic exposures were made with the subject in the supine position at intervals of 5 minutes and 30 minutes. A film with the subject standing was taken within 15 minutes after injection. Excretory urography was well tolerated, with no local reactions and only five minor gastrointestinal disturbances observed. In 12 boxers cystoscopic and retrograde pyelographic studies were necessary to substantiate urographic findings. Follow-up intravenous urograms were done within three years in 74 cases.

Supplemental Investigations.—Additional studies were made to help determine whether postbout hematuria is a consequence of the activities involved in boxing or characteristic of all vigorous exercise.

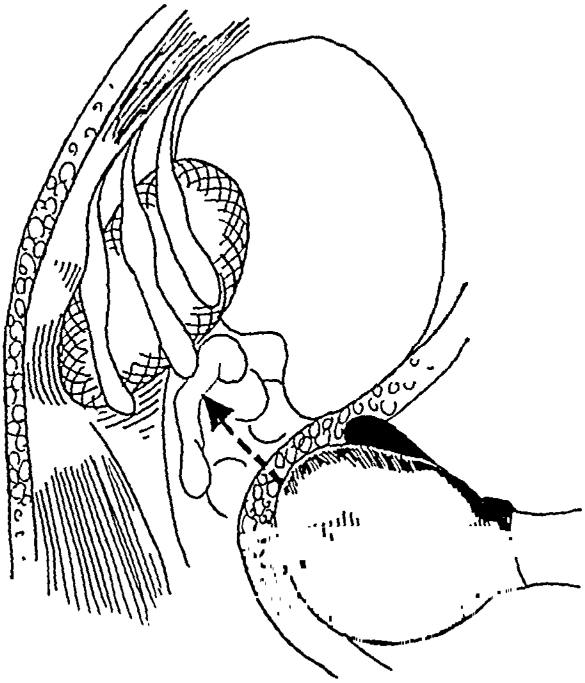

Fig. 3.—Force of direct blow to right upper abdominal quadrant shown transmitted to right kidney.

There were 132 "emergency bout" or stand-by boxers who were given standard prebout physical and laboratory examinations but who were then not called on to participate in an event. Findings in these boxers are used for comparison.

Gymnasium training for boxers consists of at least 30 minutes of strenuous exercise, including rope jumping, "shadow" boxing, and light and heavy bag punching. In order to study the effects of heavy exercise as compared with ring boxing, 100 of the boxers were chosen at random to present two-glass samples of urine immediately after such exercise. These urinary findings were charted for comparison with specimens obtained from the same subject before and after a boxing match.

A group of 20 middle-aged, retired boxers, which included 14 world champions, was carefully examined for residual urologic findings. The men had fought a minimum of 100 professional bouts during their boxing careers, with one veteran having campaigned through 527 bouts. Clinical observations included urologic history, physical examination, urinalysis, and intravenous urography. None of these men had any complaints referable to the urinary tract.

TABLE 1.—*Incidence of Hematuria in Professional Boxers*

	Preflight (2,200 Specimens)		Postflight (1,518 Specimens)	
Red blood cells/high-power field	No.	%	No.	%
1 to 5	160	7.2	571	37.6
6 to innumerable	15	0.7	415	27.4
Total	175	7.9	986	65.0
None	2,025	92.1	532	35.0

A sample of 27 men who showed consistently normal urinalyses after four or more bouts was selected for intravenous urography in order to determine whether any significant differences in morphology could be found between the men who did not bleed and those who often developed hematuria after a bout.

One hundred nonathletes, veterans of the Korean war, volunteered to participate in a study designed to filter out important factors in boxing hematuria and to determine their relative importance. Physical examination and urinalysis were performed on all the men to determine renal status. They were then divided into two groups of 50, each comprising 25 men with urinary abnormalities and 25 men with essentially negative findings on urinalysis. Each group of 50 was then subjected to strenuous jumping and bending exercises to a point of physical exhaustion for a mean exercise time of 12 minutes. In addition, the men in the second group were also subjected to 20 blows of moderate severity over the loin and abdomen. After these stresses, urinalyses and intravenous urograms were again performed on all the men.

TABLE 2.—*Incidence of Significant Postbout Hematuria According to Rounds*

	Urine Specimens,	Significant Hematuria*	
Rounds, No.	No.	No.	%
4	902	156	17
6-8	340	137	40
10 or more	276	122	44
Total	1,518	415	27 (av.)

* 6 or more red blood cells per high-power field.

Results

Clinical Observations.—Blood pressure, pulse rate, and temperature all rose substantially shortly before the pugilists entered the ring. The mean pulse rate was 84 per minute, the mean body temperature

100.4 F (38 C), and the mean rise in blood pressure 20 mm. Hg systolic and 8 mm. Hg diastolic. These changes were transient and unrelated to subsequent hematuria. A small percentage of the men also showed significant microhematuria before a bout (table 1). The emergency bout substitutes who did not box showed the same physiological elevations in the evening but had no increase in hematuria on voiding.

Table 3.—*Results of Intravenous Urography in 100 Boxers with Significant Hematuria*

	Incidence, No.	
	Right Side	Left Side
Renal Abnormality		
Excessive renal mobility	22	10
Hydronephrosis	18	9
Impaired outline of upper calyx	18	15

Ureterocele	1	...
Ureteritis cystica	1	1
Reduplication of ureter	2	1
Total	17	8

Laboratory Findings.—Significant hematuria (6 or more red blood cells per high-power field with or without albumin or casts) was demonstrated in 415 (27%) of the 1,518 postbout urinalyses obtained (table 1). This high incidence of hematuria reflected a tendency to recurrence in 237 of the 764 boxers participating in the study. No correlation was found between the presence of erythrocytes in the urine and the age of the boxers (range, 18 to 39 years). Boxing experience was likewise not a factor. The postbout hematuria rapidly disappeared. It was gone within 24 hours in 92% and within 48 hours in virtually all instances.

Gross hematuria was recorded 42 times: 30 specimens were salmon pink, 8 were bright red, and 4 were dark red. In eight cases postbout gross hematuria recurred. This symptom was more commonly found in the heavyweight than in the featherweight divisions and followed bouts of 10 rounds or more.

A marked racial difference was one of the most striking findings. Although the ratio of nonwhite to white boxers was approximately 2:1 (513 to 251), the incidence of significant hematuria was twice as high in the white as in the nonwhite boxers. It was found in approximately one of two white boxers, but in only one of four of the nonwhite pugilists.

More according to expectation was the finding that increased time in the ring increased the tendency toward significant hematuria: 44% of the boxers who fought 10 to 15 rounds and 40% of those who boxed 6 to 8 rounds, but only 17% of those going 4 rounds showed this finding (table 2).

Trauma was found to be the usual cause of hematura, albuminuria, or cylindruria. In serial studies of individual boxers with hematuria, abnormal elements were usually found after a difficult bout, although they were absent when body trauma had been at a minimum. In most instances, the abnormal elements were found to be coexisting; that is, albuminuria and cylindruria rarely occurred without hematuria.

Roentgenographic Findings.—The intravenous urograms revealed achitectural changes within the kidney which correlated with the frequent presence of hematuria (table 3). None of these morphologic changes, however, was sufficiently serious to require surgical intervention. The disorders most frequently diagnosed were hydronephrosis and movable kidney. In many instances, congenital renal anomalies were associated with significant hematuria aggravated by trauma.

Hydronephrosis (fig. 4) was demonstrated in 26 of 100 boxers with significant hematuria and occurred twice as frequently on the right side as on the left. Indeed, the preponderance of all lesions involved the right side, especially in the region of the upper calyces of the right kidney. In figure 5, urograms of a light-heavyweight boxer, with blood pressure of 128/78 mm. Hg, illustrate this. Excessive mobility involved the right kidney 22 times and the left kidney 10 times. In one case, that of a light-heavyweight boxer with gross postbout hematuria and a blood pressure of 128/80 mm. Hg, a second urogram disclosed a ptosed left kidney not discernible six months earlier.

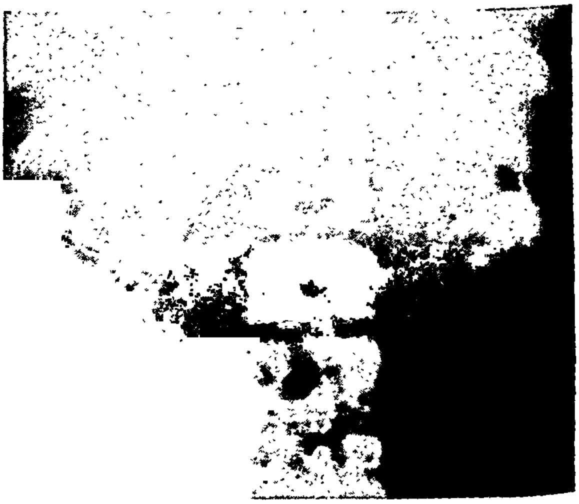

Fig. 4.—Five-minute urogram (supine position) of retired middleweight boxer who developed left renal colic during bout at 22 years of age. Note congenital bilateral hydronephrosis. Lower left major calyx is shaggy and indistinct.

A racial difference was again noted; excessive mobility occurred three times as frequently in the white as in the nonwhite boxers. The impression was gained that the perirenal fascial support is sturdier in nonwhite than in white persons, but anatomic studies are needed to substantiate this opinion.

Many of the characteristic pericalyceal deformities which are seen in urograms of both active and retired boxers are the result of a progressive process arising from repeated traumatization. The characteristic architectural deformity is the "athletic kidney." This most often involves the upper calyx of the right kidney and, to a lesser degree, the middle and lower calyces of both kidneys. In an extensive case, the entire upper calyx may be involved by distortion (fig. 6). The various types of calyceal distortion may range from scar compression with almost complete obliteration of the fornix to marked dilatation secondary to scarring at the junction of the calyx with the pelvis.

Although these urographic changes appear to be permanent, function tests with indigo carmine showed only mild impairment of renal concentration power. Fortunately, these conditions do not handicap the athlete unless accompanied by obstructing lesions. Successive urographic studies are mandatory in studying progressive deformity. They are the most accurate method employed in barring an athlete from further competitive sport.

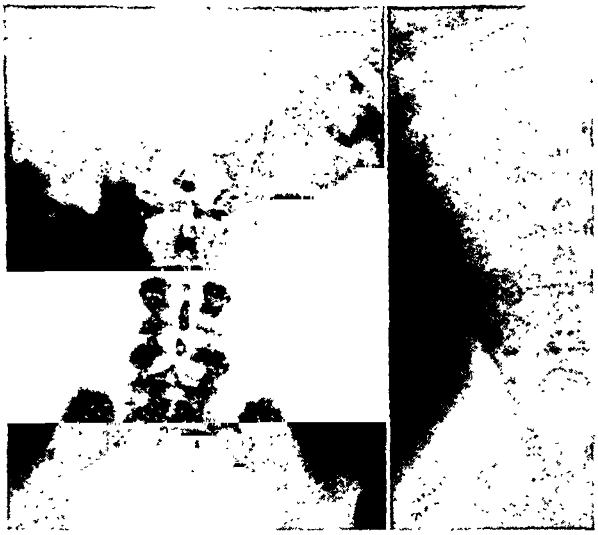

Fig. 5.—Urograms of boxer with gross hematuria after bout: *Left,* 15-minute urogram (supine position), showing dilation of right renal pelvis and upper calyx. *Right,* 15-minute urogram (upright position), showing dye trapped in upper right renal calyx.

Congenital renal anomaly (fig. 7) accounted for about one-fourth of the urinary abnormalities found. The correlation between renal anomaly, ptosis, and presence of significant hematuria was striking. I have found that these anomalous kidneys are more prone to trauma than are normal kidneys. The possible mechanism of these changes is discussed below.

A more puzzling observation was the frequent association of boxing hematuria with bleeding from other tissues. For example, 60% of the subjects who suffered postbout lacerations of the eyelid, face, or head showed significant hematuria. The possible factors producing this correlation are also discussed below.

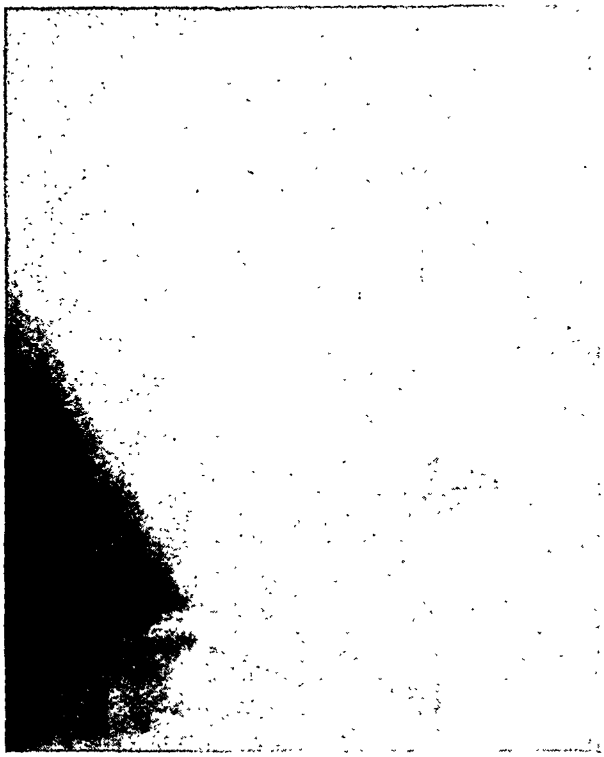

Fig. 6.—Right retrograde pyelogram, confirming irregular pericalyceal compression of stalk of superior calyx. Appearance time of indigo carmine from right kidney was eight minutes. Boxer was hospitalized because of gross, painless, postbout hematuria; he was subsequently retired.

Infections of the lower urinary tract, such as chronic cystitis, prostatitis, and posterior urethritis, were not important etiological agents in producing significant boxing hematuria. Similarly, passive congestion was of secondary importance. There were five instances of hemospermia, a condition which tends to recur in certain individuals.

Supplemental Observations.—Data for control groups confirmed the impressions obtained in the pugilists themselves that boxing hematuria is the result of the specific bodily contact and strenuous exercise characteristic of the sport, superimposed on a susceptible renal parenchyma.

Hematuria is not ordinarily elicited by the emotional stress of the competitive situation. Thus, the 132 stand-by boxers who were in readiness for competition but did not actually box had the same evening elevations in blood pressure, pulse rate, and temperature as the boxers who went into the ring. Results of urinalyses in the former group remained normal, while those in one-fourth of the over-all group indicated significant hematuria.

Similarly, exercise alone does not usually account for significant hematuria in the professional boxer. Strenuous gymnasium exercises performed by 100 professional boxers resulted in an incidence of significant hematuria of only 4%. This is in contrast to the incidence of 27% obtained in the same men after they had been in the ring.

The findings in the 100 nonathlete controls also indicate that exercise alone will not cause significant hematuria in a normal kidney. In the 25 men with completely normal urine specimens who were subjected to exercise alone, there were no instances of significant postexercise hematuria and only slight microhematuria in five. In the group of 25 nonboxers with urinary abnormalities there were 11 preexercise instances of significant hematuria. After exercise, 17 veterans showed this symptom. This increase confirms the obvious clinical impression that a preexisting pathological state greatly increases the chance that postexercise hematuria will be found.

When trauma, consisting of 20 mild to moderate blows to the loins and abdomen, was added to exercise as a provocation, the risk of hematuria in the susceptible person seemed to be slightly increased. Again, none of the 25 men with normal urine specimens before exercise and trauma showed gross hematuria after the stress procedure. But, in the group of 25 with urinary pathology, including 13 men with significant hematuria, exercise plus trauma was followed by significant hematuria in 21. A puzzling finding, however, was that the number of erythrocytes actually decreased in two subjects.

None of the 100 laymen showed the characteristic degenerative renal changes in their intravenous urograms which have been described in the professional boxers. Instead, the renal abnormalities were tumor, papillitis, pyelonephritis, essential hematuria, excessive renal mobility, and renal cyst.

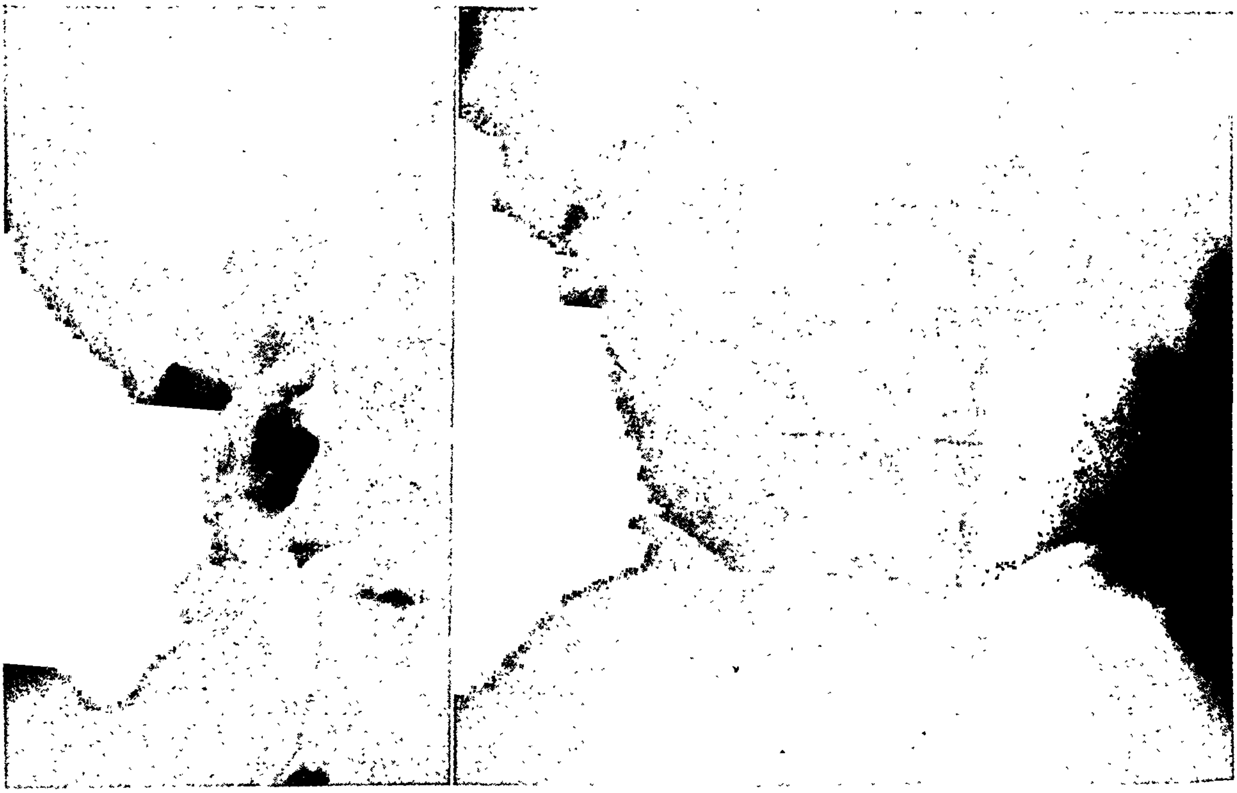

Fig. 7.—Examples of congenital renal anomaly with postbout hematuria: *Left*, urogram of featherweight boxer with congenital hydronephrosis and hydroureter on right side. Note blood clot in ureter. Athlete responded favorably to symptomatic care. *Right*, five-minute urogram (supine position) of retired heavyweight boxer, aged 23, with prebout microhematuria. Congenital absence of right kidney was confirmed by cystoscopy and aortography.

In the 27 boxers with consistently normal postfight urinalyses who were subjected to intravenous urography, fully 63% proved to have normal renal structures. In the other 37% only minimal degenerative changes of calyces or renal pelves were found, and, even in these, concentration and elimination of dye were normal.

These observations would indicate that boxing in itself does not usually produce serious renal damage. As previously mentioned, almost every instance of significant hematuria cleared within 48 hours. Observations in the 20 retired, middle-aged boxers who had fought hundreds of bouts confirm this impression. In 95% of these men, findings on urinalysis were normal. All the ex-boxers had normal pulse rates and blood pressures. Results of intravenous urograms were normal in 50% and indicated mild changes in another 30%; in only 20% were the changes considered significant. These consisted of excessive renal mobility in two cases, mild to moderate atrophy of the kidney in one, and pyelonephritis after removal of a calculus in one.

The data on the nonboxer athletes currently under study are still insufficient for formal report. Preliminary review would indicate that the findings applicable to boxing hematuria apply to a lesser degree to most other contact sports. Apparently, more cases of significant hematuria are found in football players, boxers, wrestlers, and basketball players than in hockey players.

Treatment

Trauma to the kidney should be given no less consideration in treatment than a laceration of an eyelid, for example. Boxing authorities rule that an athlete is not permitted to participate in ring activity if his eyelid shows a scar which is not sufficiently healed. Although renal tissue heals remarkably well, it seems that the required healing time of a kidney is not unlike that of the laceration of the eyelid. For this reason, a minimum rest period of 30 days is recommended for those boxers in whom significant microhematuria tends to recur. When gross hematuria occurs, a urologic investigation, including intravenous urography, is indicated. The athlete should also have successive urine rechecks, particularly after exercise. It is recommended that permission for return to ring activity be withheld until findings on urinalysis are normal. For this reason, urinalysis is performed as a standard procedure before each professional boxing match at the New York State Athletic Commission.

The physical well-being of the boxer must be considered not only for the moment but for the distant future. The physician in charge should not hesitate to bar an athlete from activity if there is any suggestion of renal pathology. Demonstration of serious renal lesions should result in the retirement of the pugilist.

Comment

Trauma to the kidney, often superimposed on congenital malformations, such as hydronephrosis, bifid kidney, and ptosis, was the most important factor in the production of boxing hematuria. It is my impression that boxing trauma may result in rupture of delicate veins within the renal papillae or pyramids.[2] The resulting hemorrhage may cause intercapillary compression about the nephrons. Later, there may be organization of a clot with proliferation of connective tissue cells.[3] The process becomes progressive if the athlete is subjected to further renal trauma without an adequate period of rest and healing. It is probable that areas of scar tissue result, thus producing the characteristic pericalyceal deformities of "athletic kidney."

As previously mentioned, this type of deformity most often involves the upper calyces of the right kidney, with the middle and lower calyces of both kidneys less frequently involved. This preference for the upper third of the kidney may result from the combined effect of repeated trauma to the flank and anterior abdominal wall, the action of the diaphragm and abdominal muscles, and the crouch position associated with the "grunt" reflex.

The frequency with which excessive mobility was found suggests that the techniques embodied in the sport of boxing may be contributing factors in this condition. The crouch position which is taken by many professional boxers in the ring predisposes to anterior displacement of the kidney. This abnormal position may tend to dislocate the kidney from its fossa, causing excessive strain on its fascial envelope (fig. 8). The "grunt" reflex employed by many boxers in delivering a blow causes the diaphragm to contract against the kidney. This is an additional factor in renal displacement. The loss of perirenal fat may be a predisposing factor to athletes in training. The superficial and deep abdominal muscles also contribute to displacement by producing reflex changes in intra-abdominal pressure. Excessive renal mobility may result in interference with venous return, producing venous stasis. The delicate distended veins in the pyramids become more easily prone to trauma. The secon-

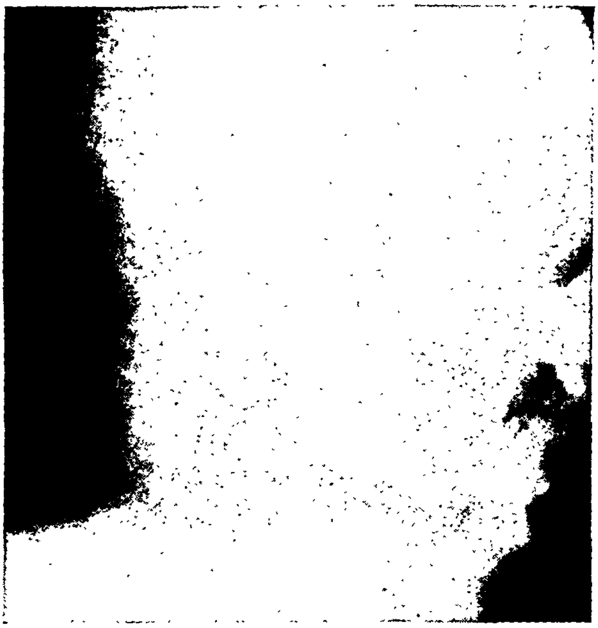

Fig. 8.—Fifteen-minute right lateral urogram of boxer in crouch position, showing anterior displacement of kidney.

darily congested nephron may develop impaired function, permitting the passage of erythrocytes and protein.

In the observation of boxers in the study, I was impressed with the fact that 60% of the subjects who suffered postbout lacerations of the eyelid, face, or head showed significant hematuria. Many seasoned veterans go through an entire career with little or no history of laceration. Other individuals "cut" easily regardless of boxing experience or the number of rounds boxed. It is possible that this correlation exists purely by chance and that a badly beaten athlete is more prone to lacerations and renal trauma. It is my theory, however, that abdominal trauma may have a direct or indirect effect on the adrenal gland or liver. As a result of trauma to these organs, a toxic, enzymatic, or hormonal product may develop within the blood stream. During the stress of activity this abnormal circulatory agent may prolong the prothrombin time or affect capillary fragility. With rest the circulatory picture rapidly returns to normal.

The data collected in this investigation may be applicable to the study of renal trauma not only in the field of sports but in accidental renal injuries as well. There is a striking degree of correlation between congenital renal anomaly, ptosis, and significant boxing hematuria. Because of inherent weakness of parenchymal vessels and fascia, the architecture of the kidney with congenital anomaly is more prone to trauma than is the normal kidney. Apparently, rupture of delicate pyramidal veins frequently results from renal trauma, initiating hematuria. Therefore, congenital anomalies of the kidney may induce a weakening of not only the supporting tissues but the more delicate vascular tissues as well. This theory should be confirmed with serial section studies of the renal tissue, a task not easy to accomplish. An appeal is therefore made to the profession in general, and to urologists and pathologists in particular, to make special serial sections of traumatic renal tissue of athletes in the operating room or on the autopsy table.

Summary

Boxing hematuria is usually an innocent, transient, and painless symptom. When it tends to recur, urologic survey is mandatory. Chronic renal trauma is the most important factor in hematuria in boxers. This condition is common in congenital anomalies and ptosis. Renal trauma does not handicap the athlete unless it is accompanied by obstructing lesions.

The incidence of boxing hematuria, renal mobility, and "athletic" kidney is higher in white than in nonwhite boxers. Further studies, including serial section of renal tissue and hematological observation, are indicated. Withdrawal from activity is paramount in the treatment of hematuria in boxers. Rest period is variable.

SURGICAL TREATMENT OF TRIGEMINAL NEURALGIA.—It is our opinion that the extradural, preganglionic neurotomy as originally advocated by Frazier and Spiller, and later improved by Adson, is the most effective surgical procedure for the treatment of trigeminal neuralgia. Properly performed, the operation is an anatomical one which gives relief from excruciating pain. Properly prepared psychologically before operation for the loss of sensation which must be incurred for the permanent relief of pain, the majority of patients do not suffer from paresthesias which interfere with their lives or the peace of the surgeon. Corneal ulceration occurs only after direct trauma to an insensitive cornea and is not the result of a trophic loss, independent of injury. Facial weakness and herpes labialis which occur immediately following operation are caused by excessive and unnecessary handling of the ganglion in the latter instance, and to elevation of the dura mater from the floor of the middle fossa too far posteriorly, in the first instance.—Daniel Ruge, M.D., Ruben Brochner, M.D., and Loyal Davis, M.D., A study of the Treatment of 637 Patients with Trigeminal Neuralgia, *Journal of Neurosurgery*, September, 1958.

SURPRISING GROWTH OF VOLUNTARY HEALTH INSURANCE IN GREAT BRITAIN

J. F. Follmann Jr., New York

Voluntary health insurance is being purchased by the people of Great Britain at an increasing rate. The schemes that have survived since 1948, when the National Health Service became effective, are generally independent legal entities serving groups of hospitals; the principal and most costly benefit now offered is a cash payment to the contributor, and in many cases to his wife, while hospitalized. Treatment in convalescent homes is the most widely provided benefit. In addition to these hospital contributory schemes, there are provident associations whose principal coverage is against the cost of maintenance in hospital private wards and nursing homes and toward the private fees of consultants, specialists, and surgeons. One such organization has increased the number of its contributors from 34,000 in 1949 to 283,000 in 1957. Analysis of the reasons for such growth reveals no reasons why it should not continue. Similar analysis of the health insurance mechanisms operating in the United States leads to the conclusion that a government approach on a broad population basis is neither necessary nor desirable.

It is a matter of interest to American physicians and surgeons, as well as others, to know that 10 years after the advent of the National Health Service voluntary health insurance is being purchased by the people of Great Britain at an increasing rate. Not only has the advent of the National Health Service failed to eliminate the various forms of voluntary health insurance, as had been expected generally, but the years since its inception have borne witness to an increasing need, and hence a demand, for privately puchased insurance.

Prior to 1948, when the National Health Service became effective, insurance against the costs of medical care was provided principally by nonprofit plans known as hospital contributory schemes. These organizations, which grew out of the Victorian Saturday funds, have distinct points of similarity to Blue Cross plans in the United States and, in fact, some consider them as the progenitor of Blue Cross.[1] Under these schemes, small amounts were collected weekly in return for which the breadwinner and his dependents were admitted to a voluntary hospital without having to make further payment. If admitted to a local authority hospital, the scheme made "some payment," thereby avoiding for the patient the required "means" test. Gradually supplementary benefits were added, such as ambulance conveyance, convalescent home treatment, loan of sick room equipment, dentures, and optical and surgical appliances.[1]

By 1947, there were some 450 hospital contributory schemes covering about 10 million, mostly low income, contributors and their dependents, this being about half the population of England and Wales.[1]

Protection was also made available prior to 1948 by nonprofit organizations called provident associations, their principal coverages being hospital and nursing home (private hospital) care and the costs of surgery, consultation, and specialists. Many of these associations were affiliates of the hospital contributory schemes, and consequently there were many points of similarity between the two.

The insurance companies in Great Britain, on the other hand, and unlike their counterparts in the United States, for the most part limited their coverages in respect to accidents and illnesses to loss of income, writing little in the way of hospital or medical cost insurance.[2]

The National Health Service

In 1948, the National Health Service became effective. Its purpose was to provide comprehensive medical care and services to all the people of Great Britain, the costs to be borne by funds derived from taxation. The services provided include hospital care, medical care provided by the physician—general practitioner, the specialist—or through public health agencies, dental care, ophthalmic care, and drugs and appliances. However, certain charges are made for certain forms of care or for certain medications or appliances. In subsequent years, the incidences for which these charges were made and the amounts of these charges have been increased, particularly with respect to dental care, drugs, and optical appliances. These charges, it seems, have been occasioned by a realistic endeavor to maintain the costs of the NHS within reason in relationship to the national income and the national budget and to limit abuse or excess usage. In addition, certain forms of care, such as that in nursing or convales-

---

Director of Information and Research, Health Insurance Association of America.

cent homes, are not readily provided by the scheme, and, if private hospital accommodations are chosen, no benefits at all then derive from the NHS in regard to hospital care.[3] These elements of the NHS are mentioned here because they have direct relationship to voluntary insurance in Great Britain as it has redeveloped and grown since 1948.

Hospital Contributory Schemes

Since the advent of the NHS, the insurance companies in Great Britain do not appear to have made any appreciable changes in their practices in respect to protection against the costs of medical care. The coverages written appear to be the same as those extant prior to 1948, namely, protection against loss of income. In addition to this, most of the hospital contributory schemes, which were part and parcel of the voluntary hospitals, had their assets taken over under the National Health Act and went out of existence. This action of the government paralleled the absorption of most of the voluntary hospitals under the NHS.

However, those schemes which survived were, for the most part, the larger schemes which were independent legal entities serving groups of hospitals. These determined to offer specific benefits to their contributors supplementary and ancillary to those obtainable under the National Insurance and Health Service acts. Two main approaches were taken. Some schemes preferred to tie the benefits closely to the hospital service. Others regarded extra hospital benefits, such as assistance toward the cost of dentures, spectacles, and surgical appliances as important objectives, these being some of the services for which charges were made under the NHS.[1]

The principal and most costly benefit now offered is a cash payment to the contributor, and in many cases his wife, while hospitalized. The purpose of this benefit is to help make good the loss of wages of the breadwinner resulting from being hospitalized and the added expenses when the wife is hospitalized. Convalescent home treatment is, however, the most widely provided benefit. Seven of the schemes own convalescent homes, 27 such homes being so owned. The other schemes contract with private convalescent homes. Since, under the NHS, convalescent home care is provided only if a patient needs medical treatment and nursing during convalescence, the interest in this benefit provided by the contributory schemes can be understood. Two large schemes provide only convalescent home benefits.[1]

The charges under the NHS for dentures, dental care, optical appliances, surgical appliances, and drugs have been mentioned. As these were established or increased, some of the voluntary schemes provided coverage to the extent of one-half the government charge. Full coverage of the charges is not provided, since this would result in abuse. Dental care benefits are limited to the partial cost of dentures, and no coverage is provided for general dental care. Many schemes had provided similar benefits prior to institution of the NHS.[1]

Contributions or premiums for the benefits are collected as economically as possible, usually on a payroll deduction basis, with some employers assisting in these payments. Another method used for the collection of contributions is the purchase of stamps on a weekly basis from tobacconists, chemists, and news agents. The government also permits its employees to have payroll deduction for the payment of contributions. Schemes operating in agricultural areas experience higher administrative costs, since individual collections, requiring the establishment of branch offices, are necessary.[1]

In 1953, there were more than 39 such hospital contributory schemes. Their total income in that year was over 2,225,000 pounds. In 1953, these schemes had 3,612,798 contributors and coverage included eligible dependents in addition.[4]

Provident Associations

The provident associations also managed to survive. The principal coverage provided by them today is against the cost of maintenance in hospital private wards and nursing homes and toward the cost of fees of surgeons, anesthetic services, consultants, specialists, home nursing care, therapy, and diagnostic services. This coverage is more easily understandable in the United States, since it has points of similarity to the hospital, surgical, and medical coverages written by insurance companies. The benefits are directed at the costs of the more serious illnesses rather than at those of minor ailments. There is an upper limit of indemnity under the coverage within each year. No benefits are available for treatment by general practitioners. Normal maternity care is excluded, and drugs, appliances, hearing aids, and spectacles are not paid for. There is a waiting period of three months for new individual subscribers but not for groups.[5] Outpatient services are subject to certain limitations as to amounts payable, and certain types of illnesses are excluded, such as normal dental treatment, mental disease, and chronic illness. All covered care must be on recommendation of the family doctor.[5]

The provident associations are reported to cater to those members of the public who want to make mutual provision for the high cost of maintenance in hospital private wards and nursing homes and for the private fees of consultants, specialists, and surgeons.[6]

The exact extent of this growth of voluntary health insurance in Great Britain is not known. One recent estimate, however, places the number at 4 million contributors who, with their dependents, are estimated to constitute one-quarter of the population of England and Wales.[1] While this estimate is by no means as great as the extent of voluntary coverage prior to 1948, being about one-half, it is nonetheless remarkable in the face of the National Health Service.

Of more significance is the rate of growth of this coverage in recent years. Enrollment in the British United Provident Association alone has increased from 34,000 contributors in 1949 to over 300,000 today.[6] Since the BUPA is the most prominent writer of coverage in Britain, this growth rate is significant. To these figures, of course, must be added the dependents of the contributors, the total, therefore, being about double the figures shown here. It is particularly to be noted that this rate of growth for the BUPA has accelerated most particularly in the past few years, as is exemplified in the table.

Over one-half of the present enrollment is now on a group basis.

Reasons for Growth of Voluntary Coverage

Several reasons are attributed to this growth of voluntary coverage. One, as has been stated, is the element of charges and the means or needs tests under certain aspects of the National Health Service. Another is the desire of a patient for privacy when ill. Still another arises out of the fact that some persons cannot afford to wait for beds in the government general wards, these waits being, apparently, a real problem of some magnitude. For example, at the end of 1956, 431,000 persons were reported to comprise the waiting list for hospital beds. The length of the waiting period varied by type of hospital and nature of illness. Hence, for general surgical cases the wait varied from 53 days in nonteaching hospitals to 70 days in the provincial teaching hospitals. For patients with ear, nose, and throat diseases, the wait ranged from 87.6 days in the London teaching hospitals to 135 days in nonteaching hospitals. A still further reason is assistance in affording private specialist treatment; there seems to be a desire for freedom of choice in the selection of surgeons, specialists, and consultants.

Not too much seems to be known about the kind of persons who are purchasing the protection. Contributors to the provident associations appear to be mainly of the middle class. Whether this is true of the contributory schemes is not known, since these contributors pay their premiums on a weekly basis and, hence, might have direct similarity to industrial or weekly premium policyholders in the United States. One opinion expressed to me was that an element of snob appeal is present in this growth of voluntary coverage. It is questionable, however, that this factor alone, or even mainly, could account for the appreciable growth of coverage since the NHS was started.

While the reasons for the growth of voluntary insurance stated here are in the realm of impression or speculation, they find substantiation in a seven-month study made in 1956 by Paul F. Gemmill, professor of economics at the University of Pennsylvania. As part of his study, Dr. Gemmill conducted a questionnaire survey of a segment of the British public and the medical profession. One question asked was this: "Do you now have, in addition to the National Health Service and National Insurance, membership in any societies or insurance schemes which, in case of illness, would pay part or all of your hospital or doctor's bills? If so, why do you feel that you need such additional 'protection' since NHS promises to provide for all health needs?" The response to this question showed that 29.8% of those questioned had such additional protection. The reasons for having the additional protection varied, but, in general, they were as follows: "extra illness cash," "subscription small and worth paying," "for private room," "for emergencies," "for extras," "for semi-luxuries," "for home help," "for private ward," "for convalescent home," "for added comforts," and "was previously a member" (this one was often repeated).[7] Certain differences in these responses might be accounted for by the differing types of coverages made available.

Rate of Growth of British United Provident Association

	Contributors, No.	Net Increase, No.
1949	34,000	...
1950	35,000	1,000
1951	44,000	9,000
1952	69,000	25,000
1953	105,000	36,000
1954	162,000	57,000
1955	214,000	52,000
1956	252,000	38,000*
1957	283,000	31,000

* Decrease in rate of growth in 1956 resulted from imposition of upper age limit of 65 on new enrollees.

Trends for the Future

There appears nothing in the picture of the foreseeable future which would indicate other than that this growth of voluntary insurance will continue. This growth might, in fact, be reasonably expected to accelerate, provided the economy remains stable. Obviously, certain changes in the nature or extent of the services provided by the NHS could affect this either way, but these do not appear to be in the offing.

There are two developments, however, which should be mentioned, since they could have marked effect on the future. One of these is a study to be made by the British Medical Association. Dr. J. Leslie McCallum, a member of the Council of the British Medical Association, has described the situation thus[8]:

> There is still a good deal of private practice and . . . there is a good deal of room for insurance-assisted private practice in the United Kingdom. . . . The British Medical Associations have decided to set up a committee of their own to investigate the workings of the National Health Service. . . . Should such a committee conclude that insurance should play a bigger part than it does now in the public service and the government accept its findings, then the situation would

> be vastly different, both for the public economy of Great Britain and for the insurance world and, of course, the doctors.
>
> For private hospital facilities there are already three or four companies who are catering for a real need for a small annual premium, and several of us on our side are drawing up schemes for grants-in-aid on insurance principles to help keep alive private practice. . . . Some of us will go on investigating such schemes as contracting out of Government National Insurance and insurance plus government cover for sickness, on the lines of the Australian scheme, with suitable tax reliefs for premiums, because we feel that there must be an alternative to govern-controlled Medicine.

The other development to which reference has been made is an outgrowth of a movement called Fellowship for Freedom in Medicine. This movement, which has no ties to the British Medical Association, appears to have as its general purpose the promotion of the private practice of medicine and the development of a scheme as an alternative to that of the NHS. Such a scheme would be based on "real insurance principles under which doctors and hospitals will charge fees for services rendered, and the bulk of these fees will be covered by insurance supported by a state subsidy; the state's contribution will be less than 50% of the charges incurred; those who cannot afford to pay insurance premiums will not be required to do so; the state will bear full responsibility for them and their dependents; and provision will also be made for reducing the heavy cost to the taxpayers of drugs and appliances."[9]

Among the purposes of the proposed scheme are that of putting more responsibility for his health on the patient, of giving him a greater influence on the quality of the services he receives, and of restoring the principles of private practice for all insured patients.[9]

It is noted that the functioning of this proposed scheme is restricted to "non-profit-making" organizations. This, presumably, would eliminate from the picture the insurance companies. The fact that no objection appears to be registered on this score is probably due to the fact, as has been noted, that the insurance companies in Great Britain have not been active in writing insurance against the costs of medical care.

In addition to these two developments, a further factor has begun to manifest itself which is of direct interest here. As voluntary health insurance has expanded, so has the demand for private hospital accommodations. However, there has been virtually no increase in the number of private beds in hospitals available to satisfy this demand, and from time to time existing private nursing homes (private hospitals) are finding themselves forced to close down entirely for financial reasons. Such a development, naturally, could eventually serve to retard the further growth of voluntary insurance somewhat unless corrected. Accordingly, the BUPA is sponsoring the financing of the Nursing Homes Charitable Trust, the object of which is to maintain and increase the number of existing private accommodations.

Comparison of Trends in Great Britain and the United States

One is impelled to strike comparison between the situation in Great Britain prior to 1948 and that in the United States in 1958. Despite obvious differences in the economy, the effects produced by two long wars, and certain differences in traditions and outlook, there appear to be certain other variances worthy of note.

One of these is what appears to have been the marked reticence of the well-established insurance companies in Great Britain to write coverages which would serve to spread the costs of medical care. This reticence had its counterpart in the United States until about two decades ago but by no means can be considered as existing today. To the contrary, the majority of Americans having voluntary health insurance protection today are covered by the insurance companies.

Another is the failure of the insuring mechanisms in Britain prior to the inception of the NHS to protect more than half of the population. Here it is recognized that in 1948 less than half of the United States population had some known protection. In the intervening years, however, this coverage has grown to about 70% in the United States and is still growing.

A third factor, somewhat related to the preceding one, was the apparent hesitancy on the part of the British mechanisms to use the group approaches on a large scale in writing their coverages. This approach is largely accountable for the rapid growth of coverage in the United States and, in fact, seems accountable for a good bit of the recent growth in the United Kingdom now that it is being advanced on a broader scale. Here, of course, the attitude of employers and labor unions plays an important role.

A final point appears to be in the quality of the insurance benefits made available. For the most part, the benefits offered in Great Britain prior to the advent of the NHS appear to have been small in amount and limited in scope, pitiably so in some cases. While they certainly offered some protection, they do not seem to have even reasonably approached offering real assistance in cases of serious illness. In the United States today, on the other hand, appreciable assistance is rendered by all types of mechanisms, particularly since the innovation and advancement of the insurance companies of major and comprehensive medical expense coverages. While the actual degree of coverage in the United States can be disputed because it is not clearly known, and while the optimum protection as a desideratum is unresolved in a maze of varying philosophies, it would seem a truism that voluntary health insurance protection in the United States today is on much firmer ground than was the case in Great Britain prior to functioning of the NHS. It is believed that this fact is often too little understood.

When one considers that health insurance in the United States is still growing rapidly, that many differing means are being employed, and that it is vital with experimentation and evolutionary development, the respective situations—the United Kingdom in 1948 and the United States in 1958—do not appear to be at all comparable. The remarkable response of the various types of health insurance mechanisms in the United States to the marked changes which have occurred in the field of medical economics would seem to stand as a clear indication that a government approach on a broad population basis is neither necessary nor desirable.

CLINICAL NOTES

EFFECT OF PREDNISONE IN THE TREATMENT OF MALIGNANT EFFUSIONS

Jorge Franco, M.D., Byron E. Hall, M.D.
and
Donald R. Hales, M.D., San Francisco

About 30% of the patients with metastatic malignancy develop significant effusions in the pleural, peritoneal, or pericardial cavities.[1] Rarely, the fluid has the characteristics of a transudate, as in some cases of mediastinal adenopathy, or a high content of fats, as in chylous effusions. More commonly, its physical properties resemble those of an exudate, with a specific gravity in the neighborhood of 1.016, a protein content higher than 3.5 Gm.%, and a high number of cells in the sediment. It was for the latter type of exudative effusions that the intracavitary administration of radioisotopes and alkylating agents was proposed; it was presumed that the effectiveness of this form of therapy was due to high local concentration of the cancerocidal agent coming into direct contact with the malignant tumor implants on the serosa surfaces.[2]

In general, it is estimated that with either radioisotopes or chemotherapeutic agents it is possible to achieve control of the effusions in about 60% of the cases; this therapy is contraindicated in patients with severe bone marrow depression and in those with loculated effusions with multiple adhesions.[3]

Since it has been shown that corticosteroids will inhibit tuberculosus effusions[4] and experimentally induced ascites,[5] it was felt that the steroids might delay the reaccumulation of fluid in malignant effusions, should an inflammatory component be present.

Material and Methods

Dosages comparable to those used for tuberculous exudates (30 mg. of prednisone per day in three divided doses) were given to 26 patients with pleural effusions (17 cases) or ascites (11 cases) secondary to carcinoma of the ovary, breast, and lung, lymphosarcoma, osteosarcoma, melanoma, adenocarcinoma of the gallbladder, Hodgkin's disease, and fibrosarcoma (neurofibrosarcoma). In all the patients the fluid had characteristics resembling those of an exudate. Malignant cells were found in the fluid of 24 patients. After what was considered the maximum effect was obtained (generally in about four weeks), the dose of prednisone was gradually decreased to reach a smaller maintenance dose, which usually was around 15 mg. a day.

Comparison of the total volume of fluid removed and number of aspirations performed over comparable periods of time, before and during steroid

---

From the Department of Medicine, Stanford University School of Medicine.

therapy, were the criteria used to determine the effect of therapy. The results were considered (1) good when there was no need for additional paracentesis; (2) fair when the need for paracentesis and the volume of fluid removed were decreased by more than 50%; (3) undetermined when the patient died during the first month of therapy; and (4) failure.

Results

In favorable cases, the clinical improvement was evident within three to five days. Roentgenologic evidence of improvement occurred within the first three weeks.

In 14 of the 26 patients, it was possible to control the reaccumulation of fluid during the administration of prednisone for periods of up to 11 months. These results are expressed in relation to the type of neoplasia and the site of effusion in the table. Rapid reaccumulation of fluid occurred in two patients on sudden discontinuation of steroid therapy. One of them responded to a second course of prednisone therapy; the other died before treatment could be evaluated. No evidence of tumor regression was observed in these patients.

Results of Prednisone Treatment in Malignant Effusions in Relation to Tumor Type and Localization of Effusion

	Results				
	Good	Fair	Undetermined	Failure	Totals
Primary Tumor					
Breast	4	1	4	...	9
Ovarian	3	...	1	...	4
Lymphosarcoma	4	...	...	2	6
Other	3	3	...	1	7
Total	14	4	5	3	26
Effusion*					
Pleural	9	3	2	3	17
Peritoneal	7	1	3	...	11

* Two of 26 patients had ascites and pleural effusion simultaneously.

Complications.—In one patient there occurred a reactivation of pyelitis, due to Escherichia coli, which was responsive to therapy with chloramphenicol. Oral moniliasis occurred in two other patients. Two patients who had histories of peptic ulcer showed no evidence of reactivation of the ulcer while receiving steroid therapy. However, they were maintained on ulcer diets and given aluminum gel prophylactically. Moderate sodium restriction and intermittent use of oral diuretics were necessary in one patient to control sudden weight gains of up to 6 lb. (2.7 kg.).

Comment

In this limited series of patients with malignant effusions, the response to prednisone therapy did not appear to depend on known sensitivity of the tumor to cortisone therapy, such as has been reported in breast carcinoma and lymphosarcoma. This, plus the lack of tumor regression, suggests that the effect was not due to direct tumor suppression. Patients in terminal condition frequently experienced varying degrees of relief of dyspnea and improvement in their general condition.

At present, it seems that the results of steroid therapy in neoplastic effusions do not depend exclusively on anti-inflammatory action. Recently, Fraisse and co-workers,[6] Riemer,[7] and Fabre[8] have independently reported favorable results with prednisone in the treatment of cirrhotic ascites and cardiac edema, conditions in which no inflammatory factor has been demonstrated. Similar effects in apparently such different situations (tuberculous effusion, malignant effusions, cirrhotic ascites, and cardiac edema) could well be related to adrenal inhibition with decrease in the utilization of aldosterone. This, however, does not seem to be the only factor, because we have followed some patients with breast carcinoma who developed proved malignant effusions several months after bilateral adrenalectomy.

The action of the steroids is probably the result of multiple mechanisms: neutralization of exudate at the site of the inflammatory response[9]; decrease in capillary permeability; changes in the electrolyte and protein balance; improvement of hematopoiesis; and possibly other factors about which little is known at present.

Summary

The most common type of neoplastic effusion occurs as a result of tumor implantation on the serosa membranes; it usually has the characteristics of an exudate; and it can be effectively controlled in about 60% of cases by means of the intracavitary administration of cancerocidal agents (radioactive isotopes and alkylating agents).

An attempt to modify the inflammatory reaction of the serosa membranes was made by means of the administration of prednisone. Twenty-six patients with neoplastic effusions were treated for periods of 1 to 11 months. The initial dose of prednisone was 30 mg. a day. After the first month it was gradually reduced to reach the smallest maintenance dose possible. Effective and rapid control of fluid was attained in 9 of 17 patients with pleural effusions, and in 7 of 11 patients with ascites.

UNIQUE MOVABLE FOOTREST FOR ELEVATION OF THE LOWER EXTREMITY

J. DeWitt Fox, M.D., Detroit

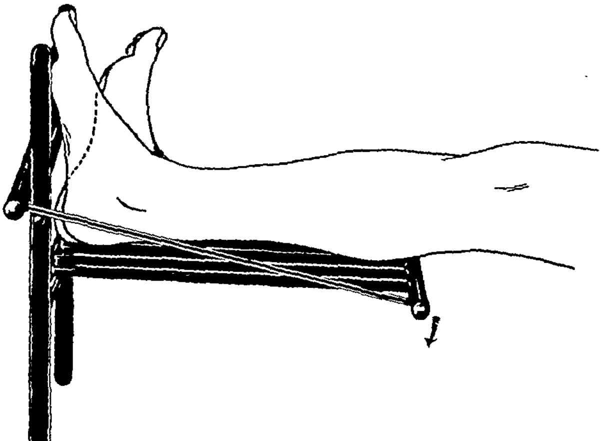
The danger of prolonged sitting without elevation of the lower extremities or movement of the legs has been stressed as a cause of venous and arterial thrombosis of the leg vessels. Homans[1] emphasized the frequency of thrombosis of the deep leg veins as a result of prolonged sitting, especially in automobiles. Tall men are peculiarly susceptible to venous thrombosis after long motor trips.[2] During World War II, Simpson[3] noted 21 sudden deaths from pulmonary embolism in persons in or leaving air-raid shelters. The cause was noted to be venous thrombosis of the legs, resulting from long periods of sitting on chairs or benches with the edges compressing the veins.

An additional modern hazard has been added to the sedentary American—prolonged television viewing, which favors venous stasis. Naide[4] has pointed out that prolonged television viewing may cause venous and arterial thrombosis in the legs and reports three cases in point.

The need for a device to prevent such occurrence prompted me to investigate various types of footrests. The one presented here is unique in design, in that it offers relaxation yet favors gentle motion of the lower extremities. One disadvantage of the ordinary footstool or hassock is compression of the calf veins. In persons with poor venous circulation, prolonged sitting without elevation of the leg or with the calves compressed against a hassock may predispose to venous thrombosis.

The need for the prevention of venous stasis while sitting is vital not only to healthy individuals with normal circulation but also to patients with a wide variety of lower-extremity maladies that require elevation of the limb. These may range from fractures of the bones of the foot, ankle, or leg to gout.

Not long ago, I had occasion to visit a friend who had thrombophlebitis. I found him sitting in the living room watching television with his affected leg elevated on a unique footrest. This device favored frequent movement of his toes and feet and prevented pressure on the calf while encouraging good venous return by the milking action of the calf muscles on his veins. The device was so lightweight, simple, and readily available that it is reported here as a valuable aid to patients requiring leg elevation or persons in good health who do prolonged standing and need a better venous return at the end of the day.



Movable footrest which tilts to the position preferred. Note that it does not hook to chair or compress calf.

The device is a portable folding footrest (see figure) that would be valuable to anyone needing elevation of the lower limb and a comfort to the person viewing television. It helps prevent venous stasis and thrombosis, since its construction favors movement of the foot and leg. It can be rocked back and forth readily while the toes of the feet are dorsiflexed and plantar flexed, thus milking the calf veins frequently and keeping quite active the circulation of the blood in the lower extremities. It does not compress the calf or popliteal area.

The rest may be moved readily. It fits any chair height or length of leg. Because it is portable it can readily be folded and carried to the office, ballgame, or picnic. This adaptability encourages the patient having a need for elevation of the leg to keep active and enjoy life to the full while caring for his leg.

If padding is desired, a pillow may be placed on the footrest for comfort. The rest is so light and is set at such an angle that it favors relaxation, yet moderate movement of the feet, in contrast to the conventional footstool or hassock, which are stationary.

Some of the conditions in which such a footrest would be of value in treatment are as follows: thrombophlebitis, phlebothrombosis (after hospitalization), varicose veins, stasis ulcer, fracture of the leg bones, ankle, and foot, cardiac or renal dependent edema, lymphangitis, contusions or injuries to lower extremities or feet, diabetic ulcer of the foot, arthritis, and after lower-extremity surgery (i. e., bunionectomy).

Prophylactically, the footrest would be appreciated by barbers, surgeons, sales persons, or anyone on his feet all day. Because it favors gentle calf motion by dorsiflexion and plantar flexion of the feet, it favors a return of normal circulation in a person having a tendency to venous pooling in the feet during the day.

Summary

A unique folding footrest favors gentle foot motion. It is an aid in the treatment of patients needing elevation of the lower extremity. It also is a comfort to persons doing prolonged sitting or television viewing to prevent venous stasis and thrombosis.

540 N. Central Ave., Glendale 3, Calif.

The footrest reported in this study is manufactured by Hamilton O. Cornwall Co., South Paris, Maine, and distributed by Breck's, Boston.

AN OVERWHELMING STRONGYLOIDES INFECTION

Harold W. Brown, M.D.
and
Vincent P. Perna, M.D., New York

Although infections with Strongyloides stercoralis are usually mild, they can be severe[1] and sometimes fatal.[2] The patient reported in this paper is of interest for several reasons. First, she had a massive Strongyloides infection, complicated by a terminal Escherichia coli septicemia and meningitis. Second, there was a lag of at least 36 years between the time of first infection with the parasite and the appearance of severe symptoms. Third, at autopsy, there was evidence of an overwhelming internal autoinfection.

Obviously, the disease must have been present for many years in a subclinical state. The intensification of her infection followed several abdominal operative procedures, but there must have been other less obvious factors also responsible for the development of the severe autoinfection.

It will be recalled that the life cycle of this parasite usually involves the passage of rhabditiform larvae in the stool. These mature outside the body into infective filariform larvae. Ordinarily they then penetrate the skin of another host, migrate to the lungs, and eventually reach the gastrointestinal tract, where they develop into the mature worms. In some cases, however, the rhabditiform larvae develop into filariform larvae before they leave the gastrointestinal tract. These filariform larvae may then invade the wall of the lower intestinal tract and migrate by the blood stream and lymphatics to the lungs. This is referred to as the autoinfection

---

From the College of Physicians and Surgeons, Columbia University.

or a hyperinfection phase of the life cycle. Autoinfection, as in this case, may eventually be associated with severe symptoms and death.

Report of a Case

The patient, a 58-year-old woman, was first admitted to the hospital in February, 1954, with massive gastrointestinal bleeding. She was born in Panama and moved to New York City 36 years ago. Since then she had worked as a beautician. An x-ray examination of the gastrointestinal tract indicated extensive diverticulosis without evidence of diverticulitis or other apparent cause for her bleeding. Her hemoglobin level at this time was 11.0 Gm. %, and her white blood cell count was 7,300 per cubic millimeter, with 76% neutrophils and 2% eosinophils. An exploratory celiotomy was performed. Extensive diverticulosis of the large intestine was found. A partial sigmoidectomy was done, accompanied by a transverse colostomy. Examination of the surgical specimen revealed only diverticulosis and chronic mesenteric lymphadenitis.

In April, 1954, the patient was readmitted for closure of her transverse colostomy. The hemoglobin level at this time was 12.3 Gm. %, and white blood cell count showed 8% eosinophils. In June, 1954, the patient had diarrhea for a day or two, accompanied by the passage of bright red blood. Her hemoglobin level at this time was 12.4 Gm. %. She had no further bleeding, but there was a continuous loss of weight from 131 lb. (59.4 kg.) to 102 lb. (46.3 kg.). In December, 1954, the patient entered the hospital for the repair of an abdominal hernia at the site of her colostomy incision. At this time her hemoglobin level was 13.4 Gm. %, and her white blood cell count was 6,050 per cubic millimeter, with 63% polymorphonuclear cells and 9% eosinophils.

Soon after her discharge from the hospital in December, the patient had episodes of vomiting, which increased in frequency. On readmission to the hospital on Feb. 3, 1955, she was vomiting four or five times a day. The vomitus, usually stained green, frequently contained recently ingested food, but not recognizable blood. On physical examination the patient weighed 90 lb. (40.8 kg.). The abdomen was not distended, and there were no abdominal masses. Four positional x-ray films of the abdomen indicated gas in the small intestine and numerous barium-filled diverticula of the colon. She was thought to have a partial obstruction in the midportion or lower part of the small intestine. A Miller-Abbott tube was passed. Her hemoglobin level was 13.5 Gm. %. She was rehydrated. On the day after her admission her serum sodium level was 121 mEq. per liter, serum potassium level 5.1 mEq. per liter, serum chloride level 94 mEq. per liter, blood urea nitrogen 25 mg. %, and serum bicarbonate level 21.6 mEq. per liter.

On Feb. 6 there was an unexplained rise in the white blood cell count from 13,000 to 23,000 per cubic millimeter. Oxytetracycline (Terramycin), streptomycin, and penicillin were given. Early on Feb. 9 she complained of a chilly sensation with her temperature rising to 100 F (38 C). She complained of headache but was completely rational. Later in the day she was found unresponsive, her neck was stiff, and she had a positive Kernig sign, a definite Babinski sign on the left, and questionable signs of a left-sided hemiparesis. A lumbar puncture revealed a cloudy spinal fluid with 8,000 white blood cells per cubic millimeter, 88% of which were polymorphonuclear leukocytes. Blood, urine, spinal fluid, and throat cultures all revealed gram-negative, extracellular, rod-shaped organisms. The patient appeared to be in shock with a blood pressure of 100/40 mm. Hg, temperature 100 F, pulse 120 per minute, and respirations 24 per minute. The abdomen was soft; no organs or masses were palpable. Later in the day there was a marked peripheral edema, and the white blood cell count was 30,000 per cubic millimeter, with 84% neutrophils. The erythrocyte sedimentation rate was 7 mm. per hour.

The organism in the blood stream and spinal fluid was identified as Escherichia coli, and, accordingly, penicillin therapy was discontinued and chloramphenical and sulfadiazine were added to her antibiotic therapy. She required levarterenol (Levophed) bitartrate for maintenance of blood pressure level, and therapy with hydrocortisone (Hydrocortone) was started. On Feb. 10 the patient became more responsive; she could answer simple questions and was aware of her environment. On Feb. 11 she was in shock, her blood pressure became unobtainable, and there was evidence of pulmonary edema. She was rapidly digitalized and also given streptomycin intrathecally. She died the same day.

The clinical diagnoses were (1) Esch. coli meningitis, (2) Esch. coli septicemia, (3) terminal pulmonary edema, (4) possible brain abscess of the right cerebral hemisphere, and (5) diverticulosis of the colon.

Autopsy

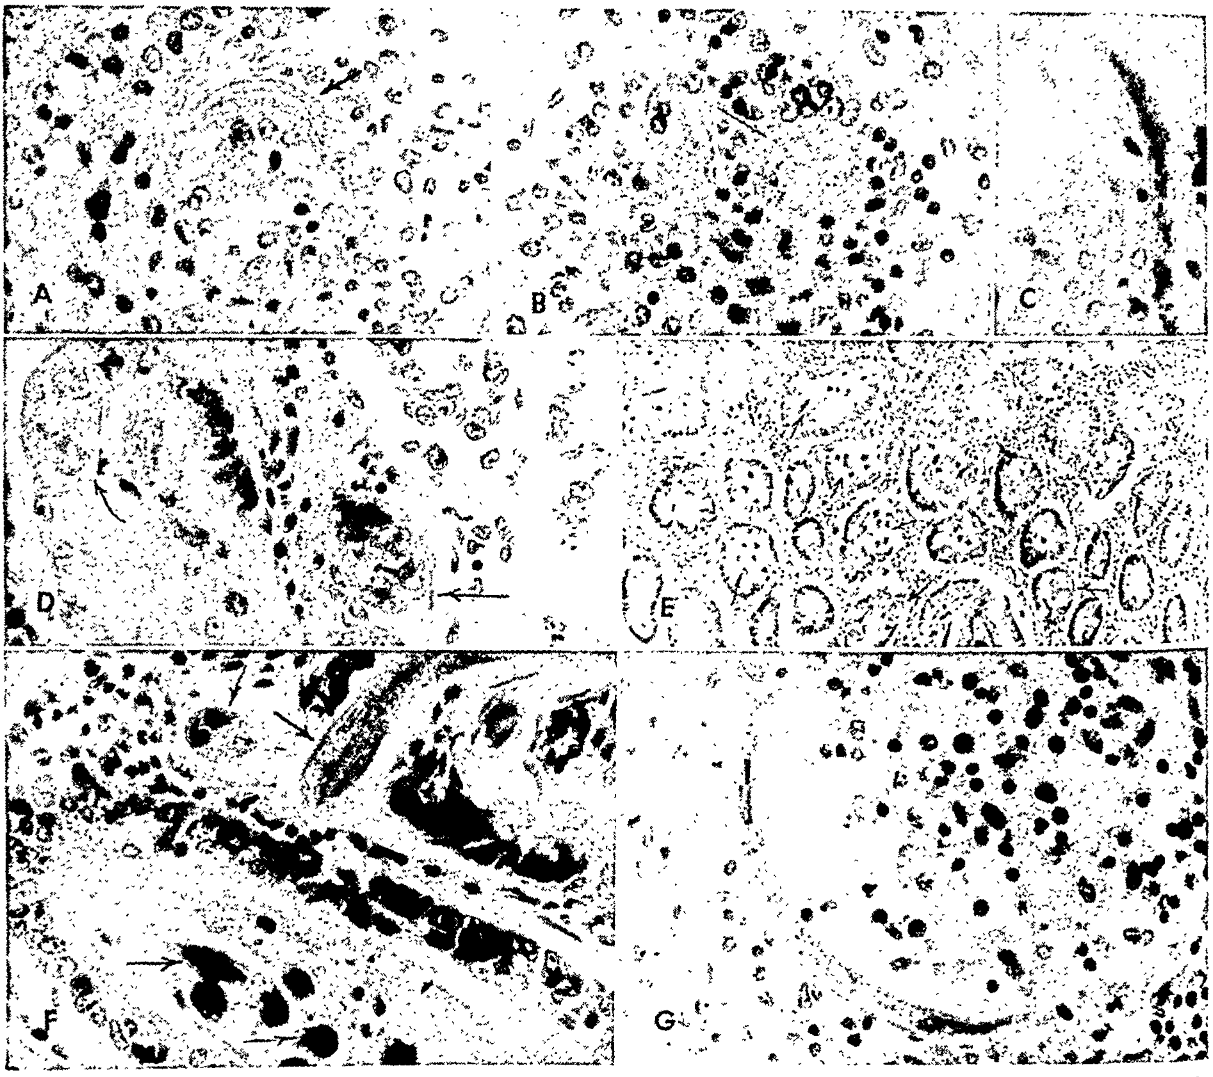
An autopsy was performed after one and one-half hours. Only the relevant pathological findings are reported here.

Gross Examination.—Each pleural cavity contained about 300 cc. of straw-colored fluid. The left lung weighed 750 Gm. and the right 875 Gm. There was extensive bilateral pulmonary hemorrhage. Grossly the small intestine was normal expect for dilation and severe edema of the duodenum and the proximal one-half of the jejunum. There were hundreds of diverticula in the colon. The mesenteric lymph nodes were four to five times average size. The subarachnoid space over the convexities of the cerebrum and cerebellum contained a profuse amount of greenish-yellow purulent material. The cisterna magnum and cisterna ambiens were filled with similar appearing material.

Microscopic Examination.—In the lungs there was extensive recent hemorrhage and scattered foci of acute lobular pneumonia associated with acute bronchitis and bronchiolitis. In addition, there were numerous filariform larvae in small branches of the pulmonary artery, in alveolar capillaries, and in the alveoli. Sometimes the larvae appeared coated with strands of fibrin, and sometimes they were marginated by a few mononuclear cells as they projected into the alveoli. No adult worms were seen in the lungs. The endothelial cells of the pulmonary arteries were moderately hyperplastic. Numerous larvae were also found in subpleural lymphatics and intrapulmonary lymphatics. They were accompanied by a mild to moderate chronic inflammatory response consisting of a few mononuclear cells, an occasional giant cell, some polymorphonuclear neutrophils, and occasional eosinophils. In some areas the eosinophilic infiltration was predominant.

There was severe, generalized fatty metamorphosis of the liver. Throughout the liver there were numerous small focal granulomatous lesions in which filariform Strongyloides larvae were found (see figure, *A*). These were in the portal areas, adjacent to portal veins, as well as within the hepatic lobules. They consisted of rounded collections of large mononuclear cells, multinucleated giant cells, polymorphonuclear leukocytes, some eosinophils, plus cellular debris and larvae. In some, the multinucleated giant cells had partially phagocytized the larvae (see figure, *B*); in others the mononuclears were surrounding the larvae. Many lymphatics in the larger portal areas also contained larvae associated with a polymorphonuclear, large mononuclear inflammatory response.

There were numerous filariform larvae in lymphatics of the portal vein, gallbladder, pancreas, adrenals, and thyroid and parathyroid glands. In the base of the gastric glands there were numerous rhabditiform Strongyloides larvae and an occcasional adult worm. The larvae were coiled and measured approximately 15 to 20 μ in diameter. In the bottom of the glands the larvae appeared to be surrounded by an acellular membrane. The larvae were also found in the lamina propria of the mucosa. Portions of adult female worms were seen also in the stroma of the lamina propria. Eggs (see figure, *D*), most of which were undergoing development, were also present in the glands and in the stroma, although some seemed to occupy an intraepithelial position. There were no ulcerations of the gastric mucosa, although the epithelium was hyperplastic. There was a moderately severe chronic inflammation in the lamina propria. There was no penetration of the adult worms beyond the muscularis mucosa.



Strongyloides infection. *A*, larva in liver. *B*, giant cell about larva. *C*, larva penetrating wall of colon into peritoneal cavity. *D*, eggs developing in stomach mucosa. *E*, larvae and eggs in duodenal mucosa. *F*, adult parasitic female and larvae in mucosa of duodenum. *G*, larva in mesenteric lymph node.

The changes in the duodenum (see figure, *E* and *F*) and jejunum were essentially similar to those seen in the stomach. In one high-power field 79 larvae were counted in the contents of the jejunum. Numerous larvae penetrated the lamina propria, the submucosa, the muscularis, and the subserosal lymphatics of the ileum. Occasionally the larvae in the muscularis were surrounded by large mononuclear cells, eosinophils, and a few polymorphonuclear leukocytes.

There was extensive diverticulosis of the colon with no evidence of diverticulitis. Numerous filariform larvae were found in the lamina propria, the muscularis, and in the subserosal lymphatics. The larvae were accompanied by the usual inflammatory response seen elsewhere. In one area larvae had penetrated through the serosa of the colon and projected into the peritoneal cavity (see figure *C*). Few larvae were present in the fecal material of the colon.

The lymph sinuses of the mesenteric lymph nodes (see figure, *G*) as well as the lymph node parenchyma contained numerous filariform larvae. Large mononuclear cells and multinucleated giant cells were marginating some of the larvae. In addition, some giant cells appeared to be phagocytizing the larvae.

The leptomeninges of the medulla, cerebellum, and spinal cord contained small numbers of polymorphonuclear leukocytes and lymphocytes. A few similar cells were seen in the walls of the leptomeningeal veins. The final diagnoses included severe S. stercoralis infection, Esch. coli septicemia, and Esch. coli meningitis.

Comment

The immediate cause of the patient's death was an overwhelming Esch. coli septicemia and meningitis. There was also a massive Strongyloides infection. The Strongyloides infection probably contributed to the patient's death in several ways. The larvae migrating in a hyperinfective cycle from the intestinal contents could have repeatedly carried Esch. coli on their surface or in their intestinal tracts into the blood stream. Such bacterial infections probably occur frequently in patients with Strongyloides infections. However, a robust person can probably control these bacteremias; otherwise fatalities in persons infected with Strongyloides would be more common. This patient, however, was debilitated and had lost 41 lb. (18.6 kg.) (30% of her weight) in a year, due partially at least to the massive Strongyloides infection. This may have been one of the factors increasing her susceptibility to bacterial infection. The massive larval invasion of many organs and especially the extensive migration of the larvae through the lungs, producing extensive hemorrhage, undoubtedly contributed to her death.

The patient lived in New York City continuously for 36 years prior to her death, and therefore her massive Strongyloides infection was, in all probability, due to the hyperinfective cycle of the parasite. It is very unlikely that infection from the soil occurred during her residence in New York. There are cases reported in which the infection has persisted for 20, 26, and 30 years, presumably without infection from an outside source. Except for the last year of her life, this patient was free of symptoms. Moreover, careful examination of serial sections of large intestine, removed at operation a year before her death, failed to reveal any Strongyloides in this tissue. However, at autopsy larvae were present in very large numbers. As many as 79 were counted per high-power field in the contents of the jejunum, and lesser numbers were counted in the contents of the colon. These findings are consistent with the activation of the hyperinfective cycle during the last year of her life after the partial sigmoidectomy. In addition, there was a gradual increase in the eosinophil count from 1% to 9% during this time. This may have been in response to an increasing larval migration.

Numerous filariform larvae were found in various tissues, and a number of them were obviously dead and undergoing necrosis and phagocytosis. It would appear that the entrapment and destruction of larvae in the tissues plays an important role in preventing overwhelming Strongyloides infections due to the hyperinfective cycle.

There has been considerable speculation concerning the existence of a parasitic male adult worm. It has been suggested that the adult male passes out of the gastrointestinal tract of the host after mating is accomplished. However, Kreis [3] reported the presence of parasitic male adult worms in the lungs of dogs. A careful examination of many lung sections from this patient failed to reveal adult worms of either sex. Over 600 adult parasitic females were collected from a portion of jejunum, yet not a single parasitic male adult worm was found.

ORAL MEDICATION WITH PREPARATIONS FOR PROLONGED ACTION

Carl A. Dragstedt, M.D., Chicago

Historical Background

Attempts to prevent gastric irritation and vomiting by enclosing irritant drugs within gastro-resistant coatings are credited to Unna and others more than 100 years ago. Some of these early coatings consisted of keratin, phenyl salicylate (salol), or gelatin hardened in formaldehyde. The preparations were called enteric, since the objective was to have them withstand gastric digestion but, nevertheless, disintegrate and undergo absorption in the intestine. These preparations were not uniformly successful, with respect to this objective. On the one hand, some soluble drugs were found able to diffuse through coatings which were satisfactorily insoluble in gastric juice, and, on the other hand, some enteric preparations were so resistant to disintegration and solution that they traversed the entire gastrointestinal tract intact. Nevertheless, such preparations continued in use and served a somewhat useful purpose. Attempts to improve upon the enteric coatings were made at sporadic intervals, but in a more or less desultory fashion, since the reasons for doing so did not appear particularly persuasive or rewarding.

As years went by, an increasing number of drugs came to be administered by parenteral injection because of various sorts of limitations to their oral effectiveness. During the era when drugs were administered virtually exclusively as oral preparations, it was recognized that various drugs varied considerably as to the duration of their effects; however, parenteral administration emphasized this distinguishing characteristic among drugs, since the gross variable due to gastrointestinal absorption presumably was eliminated. This, in turn, served to focus attention upon the fate of the drug within the body and upon the roles played by bindings, chemical change, storage in inert depots, and excretion in determining the duration of the drug's sojourn in the body and the consequent duration of its effect. More simply, parenteral administration emphasized the importance of learning the time-course of this disposal even in the instances in which mechanisms were little understood, or conversely of learning the blood levels achieved by various drug dosages and the time-course of the subsequent declines in these levels.

It was inevitable, of course, that the duration of action of a number of drugs did not coincide with the clinical or therapeutic desiderata. When the action was substantially longer than desired, attention was directed toward synthesizing shorter acting congeners; when the action was substantially shorter than desired, recourse was made to several devices. Some of these, such as the use of probenecid to impair the renal excretion of penicillin, are unrelated to the current topic. More commonly, efforts were made to delay, and thus prolong, the absorption of the drug from the injected site. This proved exceptionally fruitful. The various penicillin and insulin preparations may be cited as outstanding examples of successes in this direction.

These successes with injectable preparations reawakened interest in the possibility of modifying oral preparations of drugs so as to delay and prolong the absorption and thereby the action of the active ingredients, with the comparable objective of improving their therapeutic effects. As a result of this interest, the market is now more or less deluged with preparations purporting to have delayed action, repeat action, and sustained action. The rush to prepare all sorts of medicaments in some one of the prolonged forms has been so great that one manufacturer taunted his competitors by preparing a long-acting placebo. Before the contagion becomes too general, it seems appropriate to survey the problem in a general way.

Preparations for Prolonged Action

Manufacturing Methods.—The methods for making preparations designed for delayed disintegration and absorption will be referred to only in general terms since this is a pharmaceutical problem. Most of them fall into two categories: (1) those in which the active drug is coated with some agent more or less resistant to gastric digestion or which dissolves or disintegrates slowly in any fluid (e. g., fats, waxes, fatty acids, shellacs, glycerinesters) and (2) those in which the active drug is adsorbed on an ion-exchange resin from which it is rather slowly

---

Professor of Pharmacology, Northwestern University Medical School.

cluded. An enormous variety of agents of the first category has been studied, and their very number is something of a mute testimonial to the fact that none has been found to be uniformly successful. They are marketed in the form of tablets, capsules, and liquid suspensions. Some of them are made after the fashion of the old-time "jaw-breaker" candies of our childhood days, the alternating concentric rings of assorted colors in the candy having their counterpart in alternating rings of coating material and drug. Still others are prepared by incorporating the drug with sugar pellets or other nuclei, coating these nuclei with varying thicknesses of a selected coating material, and preparing the ultimate dose-form (whether capsule, tablet, or liquid) by assembling an appropriate conglomerate of coated and uncoated pellets. The repeat-action product is a preparation (most commonly tablet but not necessarily so) in which the two or three doses of the active ingredients that the unit contains are released at two or three presumably predetermined time intervals. Usually the first dose is released when the sugar coating dissolves and the subsequent portion when the tablet disintegrates. The sustained-action product is a preparation (capsule, tablet, or liquid) which purports to release a portion of the active ingredient relatively promptly and subsequent portions more or less uniformly throughout the ensuing period of 6 to 12 hours. Several variants to these patterns (e. g., combined types) are also available.

Advantages.—The advantages claimed for these prolonged forms of medication are obvious. Medication taken once a day instead of two, three, or four times eliminates the inconvenience for the ambulatory patient of taking medication when away from home (and thereby forgetting some doses) and saves the time of the nurses charged with distributing medicaments to institutionalized patients. A more substantial advantage claimed is that administration of these prolonged forms obviates the peaks and valleys of drug concentration in blood and tissues, which are associated with intermittent administration of ordinary preparations, and enables certain drugs to maintain their effectiveness through the bedtime hours. Thus, there are a number of areas in which the employment of prolonged forms of medication presents opportunities for improved therapeutic effects. For example, it is generally agreed that there is an increased nocturnal secretion of gastric juice in the average patient with duodenal ulcer and that most cholinergic blocking agents usually reduce gastric secretion for only two to four hours (if at all), when given in ordinary therapeutic doses. Therefore, there would be some merit to a preparation which would prolong such an action to eight hours or so. Likewise, smoothly sustained blood levels of sulfonamide compounds and antibiotics are to be desired, since the chemotherapeutic effectiveness of a number of such agents has been closely correlated with the steady maintenance of adequate blood and tissue levels of drugs.

Specific Problems.—Acknowledging the praiseworthy objective of prolonged preparations in certain fields does not, however, necessarily constitute an admission that they achieve this objective in these fields, nor constitute an encouragement to the extension of such preparations in a random or widespread manner. Some simple facts must be borne in mind, with respect to the problem. Administering a drug preparation by mouth involves many more variables than when it is injected intramuscularly or subcutaneously. It may enter a stomach with or without food, and with or without much gastric juice. It may remain there for widely variable periods of time and then be emptied into an intestinal tract, which also may vary as to the digestive juices with which it accosts the preparation and the celerity with which it transports it to the outside world. It would be rather a meaningless exercise to determine the averages of such variables, since only a minority of individuals could be expected to coincide with such averages. It seems probable, therefore, that it would be almost futile to devise protective coatings which would ensure uniform times for disintegration and absorption from patient to patient.

Campbell and co-workers[1] from the Food and Drug Laboratories of Canada have studied what they call the "physiological availability" of drugs in various preparations, by determining the percentages of administered drug that is absorbed. Using agents whose absorption could be determined with some precision (riboflavin and sodium aminosalicylate) and administering the agents by means of tablets which had varying disintegration rates when tested by a modification of the U. S. P. tablet-disintegration method, they found that "to ensure complete availability, simple tablets should have an in vitro disintegration time of less than 60 minutes as determined by the official method." On examining 11 commercially available prolonged-action preparations, they found that 10 of these had in vitro disintegration times of more than 60 minutes, indicating, by inference, that for all of these the physiologically available drug contained therein would be something less than the labeled amounts.

Their studies are sufficiently convincing to warrant the statement that a preparation which actually succeeds in delaying the disintegration of the administered form, and thereby the absorption of the active ingredient to any dependable degree, inevitably does so at the expense of some loss in precision of dosage. The corollary of this would seem to be that no drug for which precision of dosage is of paramount importance should be administered by a prolonged-type preparation. This applies to a considerable number of drugs of which the digitalis glycosides may be cited as examples.

There is a second corollary which can be drawn from their studies. When a drug is normally irregularly or incompletely absorbed after oral administration as compared with parenteral injection, it seems inevitable that this erratic behavior would be accentuated by administering it in one of the prolonged-type preparations. There are quite a number of such drugs, and they may be readily recognized by noting the marked disparity between the oral dose and the parenteral dose when the drugs are administered both ways. Several of the ganglionic blocking agents used in the management of hypertension illustrate this characteristic. A number of published reports support the contention that administration of prolonged-type preparations leads to (1) a more prolonged effect than that produced after administering ordinary preparations and/or (2) a more evenly sustained level of drug in the blood. Unfortunately the great majority of these reports state that 10 mg. of drug "X" given as a prolonged-type preparation resulted in a longer duration of clinical effects than did 5 mg. or so of drug "X" given as an ordinary preparation. Of course it should! So would 10 mg. of drug "X" given as an ordinary preparation. Only a few drugs (e. g., alcohol) have a more or less fixed rate of disposal, so that increasing the dose increases the duration of action more or less to an equal degree. Nevertheless, for the great majority of drugs, whose disposal is patterned along the lines of so-called decay curves, an increased dosage results in a definite increase in the duration of its effects, even though this is not a direct relationship. In a few studies, determinations of blood levels have been adequate enough to establish that there is less "peak and valley" rise and fall in such levels after administration of prolonged-type preparations as compared with ordinary preparations. These are quite convincing, but it should not be forgotten that *such evidence, which is valid for drug "X," cannot* be construed as applying necessarily to drugs "Y" or "Z."

Contraindications.—Mention was made previously of some areas in which prolonged-type preparations would appear to offer advantages. It is equally appropriate to mention some areas or circumstances in which they would appear to be contraindicated. In addition to the contraindications which stem from the behavior of the drug as to characteristics of absorption and duration of action, there are clinical considerations which challenge the advisability of prolonged-type preparations for certain drugs. One may include here, at least as being debatable, the employment of prolonged-type preparations for the amphetamines and other anorexigenic agents used in the treatment of obesity. In view of the lack of general agreement as to the mechanism by which these drugs have an anorexigenic action and the likelihood that they are not effective without some attendant central and cardiovascular stimulation, their employment for this purpose may be more of a price to pay than the trivial villainy of eating between meals is worth.

Still more questionable, in my opinion, is the use of prolonged-type preparations of glyceryl trinitrate (nitroglycerin) in angina pectoris. This agent has achieved its deserved reputation because it is rapidly absorbed when given sublingually and is quickly effective in relieving an anginal attack. The value of any of the nitrites as prophylactic agents is less firmly established, and the shift to a swallowed administration form is a shift to a much more erratic absorption for glyceryl trinitrate, whether coated or not. Indeed, in one controlled study, oral administration of 2-mg. capsules of the drug, four times daily, was found to be no more effective than a placebo for controlling anginal pain.[2] Moreover, the currently marketed prolonged-type preparations of this drug are viewed with grave misgivings. They are available as oral tablets containing 2.5 and 6 mg., which represent from 6 to 15 times what is generally considered to be the optimum sublingual dose of 0.4 mg. Accordingly, in view of repeated reports[3] that only minor increments in dosage beyond this optimum may produce, in occasional patients, the so-called paradoxical effect of a reduced coronary flow with attendant collapse (consequent to a venous pooling in the lower extremities and diminished venous return to the heart), the administration of such preparations assumes a degree of precision in their rate of absorption which strains one's credulity. Experience may prove that misgivings are groundless in both of these instances, but the reasons for them illustrate the attitude with which the substitution of prolonged forms for ordinary forms of administration should be viewed.

Summary

No drug whose precision of dosage is important should be administered by a prolonged-type preparation, because a bona fide decrease in disintegration and absorption necessitates an unknown decrease in physiological availability. Drugs whose normal absorption from the gastrointestinal tract is impaired or erratic should not be administered by prolonged-type preparations. The administration of drugs in a prolonged-type preparation should be viewed with misgiving if the total dose administered is more than two or three times the usual therapeutic dose, unless the drugs concerned are known to have substantially wide margins of safety between therapeutic and toxic ranges. These restrictions leave a substantial area in which there is reason to anticipate that the employment of prolonged-type preparations should offer advantages over conventional preparations. At present, there is grave disagreement as to the relevance of in vitro tests, with respect to predicting the behavior of prolonged-type preparations when administered to patients. It seems unlikely that variations in the tests will dispel this uncertainty, since the variability

between patients will remain, no matter how standardized the in vitro procedures become. The cautious physician would be wise not to become unwarrantedly optimistic as to the precision with which the prolonged-type preparations can achieve the theoretical goals envisioned for them.

COUNCIL ON FOODS AND NUTRITION

The following is one of the six papers presented at the symposium on "Nutrition in Pregnancy" in Columbia, Mo., Oct. 11, 1957. This symposium was sponsored by the Council on Foods and Nutrition, with the cooperation of the Boone County Medical Society, the University of Missouri School of Medicine, and the Adult Education and Extension Service of the University of Missouri.

Philip L. White, Sc.D., *Secretary,*
Council on Foods and Nutrition.

NUTRITIONAL STATE OF THE MOTHER PRIOR TO CONCEPTION

Genevieve Stearns, Ph.D., Iowa City

The best provision for well-being in any period of life is to arrive at that point in good nutritional and physical status. The well-born infant is sturdier throughout infancy than the baby poorly born; the sturdy infant has stores to give impetus to growth in the preschool years. The child who is in excellent nutrition will have stores to be drawn upon during the rapid growth at puberty. The well-nourished mother can nourish her fetus well; therefore, the best insurance for a healthy infant is a mother who is healthy and well nourished throughout her entire life, as well as during the period of pregnancy itself.

Present mortality statistics show that, though we have made impressive progress in lowering the death rate of children under one year of age, the neonatal death rate is still declining too slowly. The fetal and neonatal death rates, plus the number of incurably damaged infants, total a wastage that is far too high. In any study of such wastage, the conviction grows that long-term, poor nutrition of the mother is one of the most important factors. Proof of this is obviously difficult to obtain.

Importance of Nutritional Status Prior to Conception

Animal studies have shown that severe nutritional deficiency prior to conception results in death or abnormality of the fetus.[1] The deficiencies in the maternal animal are carefully graded not to be sufficiently severe to cause death of the embryos, yet sufficiently serious to cause malformations in many of the fetuses. The degree of deficiency needed to produce fetal or neonatal death, malformations, or premature delivery in the human mother cannot be determined easily. Yet both historical evidence and careful observational studies give evidence that the long-term nutritional status of the mother is an important factor in determining the health of her infant.

In any war, large numbers of people are subjected to nutritional changes usually detrimental. Smith,[2] in reporting on wartime starvation in Holland, noted that the food situation there began to deteriorate in October, 1944, and by December of that year reached a low level that was steadily maintained until liberation in May, 1945. Previous to October, 1944, rations for pregnant women and nutrition in general were fairly good. During the early part of 1945, pregnant women had available less than 1,000 calories and from 30 to 40 Gm. of protein daily. The hunger period thus represented a period of acute undernutrition after four years of regulated but reasonably adequate nutrition. Babies conceived before and born during the hunger period were shorter and weighed less than those born before this period. The incidences of stillbirth, prematurity, and congenital malformation were not significantly increased. It appears that during periods of acute hunger, after several years

---

of at least fair nutrition, the mother's own body can provide sufficient nutrients to bring her fetus to term. During the hunger period, amenorrhea was common, and too few babies were conceived for data on stillbirths, prematurity, and neonatal death rate to be statistically reliable.

The results of the Holland study were interpreted as evidence that fetal growth in weight and length was mostly affected by the mother's diet during the latter part of pregnancy. By this same criterion, the rate of development and the viability of the fetus must be affected chiefly by the maternal status well before the last half of pregnancy. Smith comments that "the results of any form of dietary inadequacy must vary in accordance with its extent in time, with the period of gestation in which it occurs, and especially with the duration of inadequacy before pregnancy."[2]

The siege of Leningrad lasted from August, 1941, to January, 1943. The food situation was at its worst between August, 1941, and February, 1942. That winter was unusually severe, with no heat available for the houses, and the food supply was both insufficient and of inferior quality. The chief staple was a bread, one-half consisting of a defective rye flour and the rest being such substitutes as cellulose, bran, and malt. The status of newborn infants was reported by Antonov[3] for 1942, compared with the data for previous years. The birth rate fell strikingly, and the stillbirth rate doubled during the first half of 1942. The incidence of prematurity increased to 41.2% of the total live births. Nine per cent of the full-term infants and 31% of the premature infants died during the neonatal period. During the second half of 1942, so few babies were born as to warrant investigation into the nutritional status of their mothers. Apparently only women able to get considerable additional food during the entire period were able to conceive during the siege. Amenorrhea was widely prevalent.

Why did the results in Leningrad differ so strikingly from those in Holland? The answer seems to lie in the fact that the women in Leningrad had not been on a regulated, fairly adequate diet regimen before the siege. During the siege they were often compelled to do outdoor work in bitter cold weather; calories ingested had to be used to maintain body heat. It seems highly probable that chronic malnutrition of some degree for a long period was followed by the acute undernutrition and malnutrition of the siege period. The fact that even the full-term infants had conspicuously low vitality, suckled poorly, and had low resistance to infection supports such a conclusion. The mothers had insufficient nutrients to give from their own bodies.

Baird[4] has commented that the conspicuous drop in stillbirth rates which occurred during World War II in the British Isles was ascribed wholly to improvement in the diet of pregnant women. Despite the anxiety and stress of the early war years, the stillbirth rate showed a drop of 3 per 1,000 births between 1939 and 1941. By 1942, the scheme of food priorities was well established, and the war situation had improved. After 1942, the rates for prematurity, congenital debility, and birth injury fell markedly. No further decrease has occurred since 1948. Baird raises the question as to whether further improvement must wait for improvement in nutrition throughout growth, resulting in better physique. "We cannot attain a minimum rate till all mothers have had the advantage of good food and environment since infancy."

A statistical survey of infant mortality in Great Britain in relation to social class[5] also brought out the marked drop in stillbirth and neonatal mortality discussed by Baird. Yet, though over-all lowering was impressive, the relative distribution of these early deaths among the five economic classes had not changed. The gap between the death rates for professional and managerial classes (class 1) and unskilled workers (class 5) was as wide in 1948 as in 1928, though the whole curve showed a steady decline. Since all pregnant women during the war showed improved nutritional status, these relative differences were ascribed, at least in considerable part, to the poorer lifetime nutrition of the mothers from the lower class.

Thomson,[6] in an ingenious study planned to assess the results of lifetime diets, reasoned that girls always well nourished in all nutritional essentials would grow to the full height that their heredity would permit and would be in vigorous health. On the contrary, girls ill-nourished throughout all of childhood would be somewhat stunted and in poor health. If a large number of pregnant women were to be studied, the influence of these factors could be distinguished. A survey of nearly 3,500 primiparas in Aberdeen, Scotland, showed minimum prematurity rates (32 per 1,000 live births) and neonatal death rates (19 per 1,000 live births) among infants born to mothers 64 in. and over in height and in good general health. Significantly higher rates (91 per 1,000 and 37 per 1,000 live births, respectively) were found among infants of women who were both small in stature (under 61 in.) and in unsatisfactory health. Several hundred women were included in each group.

In the United States, Burke and collaborators have studied the relation between diets of mothers and the physical status of their successive siblings. The authors state that "all of the stillborn infants, all of the neonatal deaths but one, all of the premature infants but one (a neonatal death), all of the functionally immature infants, and most of the congenital defects were found in the group of infants born to mothers with 'poor' or 'very poor' prenatal diets. Since no major effort was made to change the dietary habits of these women, it is probable that in the majority of cases the prenatal dietary rating was representative of long-time food habits." When the diet histories showed that the food habits of the mothers had improved materially before the birth of the second sibling studied, the condition of these second infants was also improved; if the mother's diet had deteriorated, so did the condition of her infant, compared to his earlier born sibling.

In a recent review, Garry[8] stressed the fact that pregnancy and lactation, though normal processes, do provide additional stress. A diet just satisfactory for the nonpregnant woman may be insufficient for her during pregnancy.

Studies of indigent pregnant women in Iowa have shown that the diets ingested by pregnant women do not differ conspicuously, except in quantity, from their lifetime diets.[9] With few exceptions, a woman whose diet is poor in pregnancy can be considered as having had a poor diet since early childhood. Conversely, a woman whose dietary habits are good when she enters pregnancy usually has been well nourished throughout life.

Of 404 women studied, only 37 ingested more than 75% of the amount listed in the National Research Council's Recommended Dietary Allowances (1948 edition) for each of the 10 nutrients studied. Many of these 37 achieved sufficient amounts of the given nutrients only at the expense of excessive caloric ingestion, for their food choices included too much carbohydrate food. The diets of 110 women were classed as poor, and 76 were classed as very poor. Though only 29 women ingested less than 1,800 calories daily, 44% of the entire group of 404 women was classed as poorly nourished, the remainder having fair to excellent nutrition.

Three per cent of the 227 women with fair to excellent dietary habits delivered single infants prematurely.[10] Usually, these women had had five or more pregnancies in rapid succession. Such a woman needs unusual care given to her nutrition in order to avoid depletion. All the infants were in good condition, and the smallest weighed 1,970 Gm. (4.3 lb.). In contrast, 10% of the 177 mothers in the group who had always been poorly nourished delivered prematurely. One infant was stillborn, 4 were born with severe congenital anomalies, and 5 of the 10 infants born alive died within the first week. Six of the 12 mothers whose diets were the poorest and who delivered prematurely were under 21 years of age. It was the first pregnancy for five of the mothers and the second for the sixth mother. These young mothers were not physiologically equal to the task given to them. Their dietary histories gave evidence of poorly chosen diets since early childhood.

Nutritional Status of Women of Childbearing Age

In the United States, it appears that in all strata of society the adolescent girl has the poorest diet of any member of the family. The urge for slenderness and the compulsion to do as the group does result in the girl's refusal to eat nutritious food at home; yet she snacks frequently at the gathering places for her group. The result too often is the ingestion of a decidedly unbalanced diet. Milk is eschewed because it is considered fattening. High-carbohydrate snacks are ingested at such times that appetite for meals is destroyed; however, the food ingested does not satiate, and more snacking is indulged in, often to the point of obesity. The girl is malnourished, and her plane of nutrition is low.

At the State University of Iowa, a group of adolescents with severe dental caries was studied. An unexpected time-lag in the improvement of the incidence of caries was found in the group when given a good dietary regimen. Such a time-lag indicated that the amount of time required to raise a subject to a higher plane of nutrition might vary with the length of time the subject has been maintained in poor nutrition and with the relative difficulty of absorption and utilization of the nutrients involved. To accomplish an increase in absorption of those nutrients normally absorbed with some difficulty, such as calcium and iron, might take more time than to achieve an increased absorption of those nutrients readily soluble in water which are rapidly and completely absorbed. For these reasons, we studied the retention of calcium, phosphorus, and nitrogen by three groups of girls from 11 to 18 years in age.[11]

All the girls had received an adequate amount of calories. The diets of the first and third groups were considered as only fair, although they did contain one and a half pints of milk daily and were better diets than many children receive. The second group had had an excellent diet for at least four years. When the first and second groups were given a series of increasingly good diets, the well-fed girls utilized the nutrients better, as evidenced by a calcium retention nearly double that of the previously less well-fed girls. We had expected the opposite. It took five months for the group previously having poorer diets to equal the daily retention of the group with consistently good diets when both were on the same dietary regimen.

The third group, comparable nutritionally to the first group, was given a standard dietary regimen including a quart of vitamin D milk daily with ample amounts of protein, calories, and vitamins. Calcium retention, although poor at first, increased steadily. After five months of this regimen, the mean retention values were as high as those of group 2. During the final four months of the study, each girl maintained a daily calcium retention ample enough to achieve and maintain a well-calcified skeleton.

Another unexpected finding in this study was that emotional disturbance resulted in a prompt decrease in calcium retention by each girl, regardless of previous diet or nutrition. The amount of decrease in retention tended to parallel the degree of emotional upset. The emotional instability of adolescents is well known and undoubtedly is a major factor contributing to their malnutrition, particularly that of girls.

Many of these young girls who have always lived on a low nutritional plane will enter marriage with no nutritional training, with their own nutritional stores incomplete, and with the emotional instability of adolescence often at its maximum. Can this girl's body, inadequately nourished and with no reserves, provide nutrients for another body and at the same time build up her own uterine and abdominal musculature and the other tissues necessary in pregnancy?

A study of girls and young women illegitimately pregnant, aged from 13 to 30 years, was then undertaken in our laboratory to determine whether pregnancy itself increased the ability of the girl to absorb and retain nutrients, whether emotional distress was an important factor during pregnancy, and whether increased age of the mother altered either of these factors.[12] The educational status of the subjects varied from grade-school to college students. Throughout the age range studied, all emotionally stable subjects were able to absorb and retain more nutrients than were needed by the fetus. Girls from the poorest nutritional backgrounds were able to retain as much as girls whose nutritional background had always been good. Pregnancy itself, therefore, increases the utilization and storage of essential nutrients, provided that they are ingested. Unfortunately, the sensitivity to emotional distress remains; retention values reflected each disturbing influence. The subject most continuously disturbed over her situation lost calcium steadily during the study. Her total calcium loss was at least double the amount used by her fetus. Her losses of phosphorus and nitrogen were less striking but left her body with a serious deficit.

If the young pregnant woman remains emotionally stable and ingests a good diet, she is in an excellent position both to improve her own nutritional status and to produce a sturdy full-term infant. Obviously, the earlier in pregnancy her nutritional habits can be improved, the better for both her infant and herself.

The girl who marries during her mid-teens is apt to be a girl poorly nourished through most of her lifetime and to be equally ill-equipped to meet the many psychological problems inherent in establishing a successful marriage and the new family. It is not surprising, therefore, that she is the least successful mother in producing a healthy full-term infant. These young adolescent girls greatly need counseling in nutrition and in the whole area of preparation for successful family life.

Nutrition Education

The nutritional status of any person may be improved at any time of life, provided that the needed nutrients are available and interest is aroused toward improving the nutritional status. At what ages are chances for success best? Nutritional habits of families tend to remain relatively constant for generations, a fact particularly true among lower-income families. If the adolescent breaks with family tradition, it is usually in the direction of poorer nutrition. Marriage usually returns the new family to the traditional pattern, modified somewhat by the food likes and dislikes of the spouse.

Within the family, the infant occupies a favored position. The public is educated to expect supervision of the baby's nutrition, and free clinics make this possible. After the child can feed himself at the family table, his nutritional status is apt to deteriorate. The family needs further education concerning the nutritional needs of children during the preschool years. The grade-school child is active, hungry, and relatively uncritical in matters of food. The adolescent boy asks only for quantity. The adolescent girl prizes social status above all, and she will sacrifice everything to achieve a slender, well-dressed appearance and to conform to the habits of her group. The younger the child, the easier it is to change his habits in the direction of improvement in nutrition. His response to diet is also more rapid than that of the older child. The adolescent with a poor nutritional background, emotional instability, and insistence on conformity with the group has the greatest need but is the most refractory to nutrition education.

It appears that the two ages most amenable to change in dietary habits are the grade-school child and the young pregnant woman. If taught good nutritional habits in school, usually the child insists that the parents follow directions, for school, at that age, is gospel. The teaching of nutrition in school at this age throws the burden on the already overworked teacher or school-lunch supervisor, but much can be accomplished. The adolescent girl must be approached through the medium of beauty and popularity, not nutrition per se. If improvement in diet can be made fashionable among her own group, the chance for success is improved. Too often, however, knowledge of nutrition learned in the grades is discarded by the high-school girl.[13]

The importance of good nutrition in this group is so great that no steps toward its improvement should be neglected. Organized groups for teen-agers, such as Girl Scouts, 4-H Clubs, Camp Fire Girls, and others of like nature, should be encouraged to stress good nutrition and to give credit for its achievement. Nutritionists must learn the proper psychological approaches for teen-agers. School lunches should conform to good nutritional standards, and, most of all, nutritious foods should be made more easily available than their poorer counterparts. The substitution of milk-dispensing machines for soft-drink dispensers when tried has resulted in improved nutrition. When the school may receive a larger percentage from the sale of soft drinks, often this change is not made because the penny in the pocket is more valuable than the health of the child. If the school does not practice what it preaches, how can we expect the children to exceed our wisdom?

The young woman in her first pregnancy wants help, and she wants a healthy baby. If she is not interested in her own nutrition, such interest can often be stimulated by discussing with her the chances of lessened trouble for herself and the increased ease of care of her infant.

Pregnancy is a time when a woman seeks medical advice early. Nutritional advice well-presented in early pregnancy is more apt to be taken. If the habits of the community are such that the mother comes to the physician only in late pregnancy, dietary advice is still advisable. All such advice must be geared to her previous food habits and to her purse, or it will not be used. In other words, her diet must be improved but not changed entirely. A printed diet list is useless unless accompanied by full discussion of how it can be fitted in with the mother's customary food habits.

No discussion of diet improvement in the young mother is complete without including a discussion of the dietary habits of the prospective father. Often he is the chief stumbling block to improvement of the mother's diet or that of the family. He often has strong food prejudices and adheres to them at least as stubbornly as his wife to hers. Since young children are apt to imitate their father's habits, his influence on the family's nutrition is important.

If the prospective father can be convinced that it is an essential part of his duties as a father to see that his wife eats the food proper for production of a healthy infant, that it will be necessary for him to eat the same food in order not to increase her work unnecessarily, and that he will in no way be harmed by such a diet (in fact, it may even help the next baby), young fathers-to-be are more docile about changes in their own food habits. In practice, if each parent tends to guard the other's diet, both improve their food habits. If both parents eat a thoroughly good diet for eight months, the pattern is set, and another family is started in good nutritional habits. Each family trained in good nutritional habits increases the number of well-born infants.

Summary

It appears certain that pregnancy wastage and neonatal mortality are greater when the nutrition of the mother is habitually poor. It seems highly probable that further decrease in stillbirth rate and neonatal mortality will follow improvement in lifetime nutrition, which is desirable at any stage in the reproductive or the life cycle. If the nutritional level of the mother is low, improvement of her nutrition, even in the third trimester of pregnancy, improves the status of the infant.

The ideal situation is the maintenance of excellent nutrition from conception throughout life. The American public is thoroughly educated only in regard to infant nutrition but needs the same thoroughness of education for each age group throughout life. At present, the nutrition of adolescent girls, the age group least amenable to nutrition education, is usually poorer than that of younger children, although their needs are high. Children of grade-school age and pregnant women, if properly approached, seem the groups most receptive to nutrition education. Of these two groups, the latter is more generally available to the physician. Serious efforts should be made to provide nutritional education to all ages, wherever and whenever possible.

DYSMENORRHEA

ALTHOUGH theoretically menstruation should be a painless physiological function, many apparently normal young women have dysmenorrhea. In fact most women have some cramping, but, considering it normal, pay little attention to it. Because of its subjective nature the intensity of this pain is hard to evaluate. Estimates of the incidence of dysmenorrhea vary widely. Smith and Norris [1] state that it affects about 35% of all women but in most of these it does not seriously interfere with their activity. It is a great nuisance for employers, and some industrial surgeons believe it is used by some as an excuse to obtain time off. This idea would seem to find some support in the fact that Smith and Norris found that about 16.5% of the women in an industrial survey required time off for this reason whereas in a survey of high school and college girls the incidence was only about 3%.

Dysmenorrhea may be secondary to such conditions as cervical stenosis, pelvic inflammatory disease, uterine tumors, and endometriosis, but when no specific cause can be found the symptom is considered primary. Most cases fall into the latter category.[2] A psychological element appears to play a large part in the production of menstrual pain. Patients with dysmenorrhea in general were less well adjusted emotionally as children and showed more anxiety in connection with bodily functions than nonsufferers.[3] An exaggerated fear of recurring cramps followed by cramps may set up a vicious cycle and result in a morbid dread with an aggravation of all symptoms. The mechanism of the pain has been shown to be similar to that of angina pectoris—spasm producing a temporary local ischemia. The pain is usually maximal at the onset and accompanied by a scanty flow. As the spasm relaxes a normal flow is established and the pain disappears. In severe cases the patient may have nausea, vomiting, and syncope. Dysmenorrhea may become much less severe after marriage or childbirth, but this is not always the case.[4]

Treatment requires patience, skill, and sympathy. Before any definite course of treatment is tried it is important to get a complete history including information about the usual diet, occupation, and exercise taken.[5] Examination should include observations of posture, hemoglobin determination, and basal metabolic rate and other tests of thyroid function. Any organic causative factor discovered should be specifically treated. Smith and Norris found that if working girls know that provisions for their relief are available at work there is less absenteeism. Often this need be no more than a place to rest, a hot drink, a hot water bottle, and a mild analgesic. Further evidence of the psychic element in this disease was apparent in Arthure's [4] findings. Although he found that 69% of his series got relief by taking ambucetamide (dibutamide), 48% were relieved when a placebo was substituted. Chamblin and Corbit [6] also found that in those whose pain was only moderately severe a placebo and reassurance helped, but this type of help could not be relied on every month. He found that chlorpromazine could be substituted for codeine with equally satisfactory results and since chlorpromazine is not habit forming this was considered advantageous. The chlorpromazine was especially effective in those with tension, anxiety, and nausea. Because progesterone relaxes the uterus it has been tried but with generally poor results. Diethylstilbestrol is cheaper and much more effective; 1 mg. given every night for 15 days before the expected onset of menstruation suppresses ovulation but not menstruation. It has been shown that nonovulatory periods are painless and this may explain why in some patients menstrual periods are painful only every second month. If diethylstilbestrol produces undesirable side-effects, conjugated estrogenic substances, ethinyl estradiol, or promethestrol dipropionate may be tried.

If endocrine treatment fails a stem pessary used for two or three months may give relief lasting about a year, but such a course is rarely necessary. As a last resort in patients who are severely disabled by their cramps and who can obtain relief in no other way, Arthure recommends presacral neurectomy, first used for this purpose by Cotte.

In his series 50% were permanently and completely cured and most of the rest were greatly improved. Division of the sympathetic nerves supplying the uterus may interrupt pain fibers, cut off the efferent motor fibers inducing the spasm, or cause vasodilatation in the uterus. Any of these factors could give relief. It would seem, therefore, that if the proper treatment is applied to the individual patient relief can be obtained unless an element of malingering is present. Although we cannot yet prevent dysmenorrhea we can alleviate suffering from this condition when it occurs.

NATIONAL MEDICAL-LEGAL CODE

The new National Interprofessional Code for Physicians and Attorneys appears on page 1663 of this issue of The Journal. It was adopted by the American Medical Association and the American Bar Association in June and August, respectively, at their Annual Meetings this year. This Code was prepared by the Joint A. M. A.–A. B. A. Liaison Committee after a study of interprofessional problems and after reviewing the numerous codes previously adopted by state and local bar and medical associations. The medical members of this Committee were Drs. David B. Allman of Atlantic City, N. J.; Hugh H. Hussey of Washington, D. C.; and George M. Fister of Ogden, Utah. The law members were Judge Frank C. Haymond of Charleston, W. Va.; Lewis C. Ryan of Syracuse, N. Y.; Joseph H. Gordon of Tacoma, Wash.; Fred B. Helms of Charlotte, N. C.; and Bernard G. Segal of Philadelphia.

The need for this National Code, which is intended as a guide for physicians and attorneys in areas where they have mutual interests and mutual problems, is obvious from the fact the from 65 to 80% of all cases tried today require medical testimony. In addition 7 out of 10 personal injury cases are decided on medical rather than legal considerations.

The first interprofessional code of record was promulgated by the bar association and medical society of Cincinnati in 1954. Since then over 25 state and county bar and medical associations have entered into similar agreements.

The National Code is very much like many of the state and county codes. It does, however, contain one section generally not found in previously adopted codes, namely, a section relating to the handling of a complaint or criticism by a member of one profession against the other. This section has been included because of the realization that the public airing of criticisms and complaints by members of one profession against the other neither improves interprofessional relations nor enhances either profession in the public's eye.

The adoption of this National Code is a milestone in the development of a better rapport between physicians and attorneys. It is now up to individual members of the profession to adhere to these rules of conduct. Such adherence will inevitably mean that the general public will be better served by the members of the legal and medical professions.

THE MINNEAPOLIS CLINICAL MEETING

The Clinical Meeting of the American Medical Association has established itself as one of the important medical meetings in the United States. The program, which formerly was geared specifically to the physician in general practice, has been broadened to include the interest of the specialist.

One of the features in Minneapolis will be 10 breakfast meetings at which topics of special interest to all physicians will be discussed under the direction of outstanding moderators. Physicians should obtain their tickets in the Registration Area in Minneapolis Auditorium as early in the week as possible, because attendance in each group is limited to 30 persons.

Lectures, panel discussions, symposiums, motion pictures, color television, and scientific exhibit demonstrations fill the daytime hours completely. Color television will originate at the University of Minnesota Hospital and will be shown each morning and afternoon in Minneapolis Auditorium. A Trans-Atlantic Conference on Chest Diseases will be one of the highlights of the meeting. Since the British Medical Association is holding its first clinical meeting at the same time as the A. M. A. Clinical Meeting, a two-way transoceanic telephone hookup is planned between a panel of American physicians in Minneapolis and a panel of British physicians in Southampton. The Scientific Exhibit will run continuously from 8:30 a. m. to 5:30 p. m. with demonstrators on duty to discuss their exhibits and to answer questions.

The history of medicine in Minnesota will be depicted in four booths, showing many interesting facts about early progress in medicine.

Demonstrations on the problems of delivery will include the use of a manikin. This feature will be presented at certain intervals during each day, and will offer an opportunity for questions and personal consultation with the demonstrators.

All scientific activities will take place in Minneapolis Auditorium with the exception of the breakfast round tables and the evening motion picture program.

The local committee has arranged interesting entertainment for Tuesday and Thursday evenings, while on Wednesday evening a film symposium on proctology for the general practitioner, with discussion by experienced proctologists, will be presented.

The local committee in Minneapolis, working with the Council on Scientific Assembly, has prepared an outstanding program which is a real contribution to graduate medical education.

ORGANIZATION SECTION

ESTIMATES OF COSTS FOR MILITARY CARE BY THE BUREAU OF THE BUDGET

June 27, 1958

William J. Kennard, M.D.
Acting Director
American Medical Association
Washington Office
1523 L Street, N. W.
Washington 5, D. C.

Dear Dr. Kennard:

This is in reply to your letter of June 17, 1958, requesting the Bureau of the Budget to furnish you the results of the survey made to bring up to date estimates of the costs of caring for military dependents in military hospitals which were furnished to you last year. I am glad to comply with this request, but it should be understood the data furnished herewith are based upon a somewhat limited coverage of costs in military hospitals and the application of informed judgment to the basic information.

On the basis of a detailed analysis of the proration of direct operating costs between care of dependents and other patients made at 14 representative military hospitals for the fiscal year 1957, it is concluded that the direct cost of dependent care averaged $31.58 per patient day.

The following items of indirect cost, averaging $8.38 per patient day, have been added in order to arrive at an approximation of the full cost to the Government of providing medical care to dependents in military hospitals. Depreciation of buildings and fixed equipment, $1.90; operating costs of central procurement and supply distribution system, $0.57; cost of education and training to increase proficiency of hospital personnel in patient care, $0.51; cost of headquarters staff management and professional direction incidental to inpatient care of dependents, $0.17; medical care of military personnel and their dependents, $1.06; retirement benefits of military personnel, $1.17; and outpatient care incidental to hospitalization of dependents, $3.00.

The combined direct and indirect costs result in a total estimated patient day cost for dependent care in fiscal year 1957 of $39.96. Of this amount, $34.46 represents the cost of hospital care and $5.50 approximates the cost of staff physician's services. To reflect current costs, it is necessary to add to this 1957 experience the increased operating expenses incurred in fiscal year 1958 plus the cost of the recently granted pay increases for military and civilian personnel. These items are estimated to be $2.00 and $1.71 per patient day respectively. The total current cost for care of dependents in military hospitals, therefore, is estimated to be $43.67, comprising $38.05 for hospital care and $5.62 for staff physician's services.

Sincerely yours,
Roger W. Jones
Assistant Director

ANIMAL CARE MEETING

Better care for research animals means greater accuracy in scientific findings. This is the idea underlying the Animal Care Panel whose ninth annual session will be held at the Hamilton Hotel, in Chicago, Dec. 3-5. The panel is a volunteer organization and has no staff. Its efforts are aided by the National Society for Medical Research, which publishes its proceedings. Sessions are devoted to the exchange of technical information offered by scientists and laboratory animal superintendents on matters of colony management.

Areas of discussion to be covered during the three-day meeting will include the following: techniques and equipment in maintaining germ and pathogen-free colonies; design of animal quarters and temperature control; management of sanitation and nutrition; and diagnosis of diseases in laboratory colonies.

MINNEAPOLIS CLINICAL MEETING

One of the features of the Minneapolis Clinical Meeting will be 10 breakfast round tables on Thursday morning, Dec. 4, on subjects of paramount interest in the practice of medicine. Attendance at each round table will be limited to 30 persons. Tickets will be available at $2.50 each, as long as the supply lasts, in the Registration Area at the Minneapolis Auditorium, beginning Tuesday morning. Physicians are urged to purchase their tickets as early in the week as possible.

Breakfast begins at 7:30 a. m. and the conference terminates at 8:45 a. m. allowing time to reach the Auditorium for the program there.

The subjects to be discussed at each breakfast, the moderators, and the place are as follows:

Obstetric Emergencies.
  Roy G. Holly, Omaha.
    Leamington Hotel, Indiana Room.
Problem of Management of Severe Sepsis.
  Wesley W. Spink, Minneapolis.
    Leamington Hotel, Michigan Room.

Orthopedic Problems in General Practice.
John F. Lyford III, Hines, Ill.
Leamington Hotel, Chicago Room.
Common Problems in Managing the Arthritic Patient.
John W. Sigler, Detroit.
Leamington Hotel, Twin Cities Room.
Cancer Detection in the Doctor's Office.
David P. Anderson Jr., Austin, Minn.
Curtis Hotel, Moroccan Room.
Management of Jaundice and Liver Disease.
Cecil J. Watson, Minneapolis.
Curtis Hotel, Mirror Room.
Acute Poisonings.
Robert D. Semsch and Warren R. Lawson, Minneapolis.
Curtis Hotel, Solarium Room.
Current Trends in Legal Medicine.
Raymond A. Scallen, Minneapolis.
Curtis Hotel, Evergreen Room.
Infant Resuscitation.
Ellis N. Cohen, St. Paul.
Curtis Hotel, East Room.
The Practitioner and the Medical School.
Walter S. Wiggins, Chicago.
Curtis Hotel, Vermilion Room.

SUMMARY REPORT ON HEALTH AND INSURANCE PLANS UNDER COLLECTIVE BARGAINING

What types of health benefits are being negotiated under collective bargaining agreements? What is the extent of coverage under such agreements? What appears to be the future trend in the negotiation of such agreements? What are some of the gaps of coverage as reported by a recent government study? The answers to these and other questions which have been raised by physicians can be found in a new publication just issued by the Committee on Medical Care for Industrial Workers of the Council on Medical Service and Council on Industrial Health. The publication, entitled "A Summary Report on Health and Insurance Plans Under Collective Bargaining, Late 1955" is based on a report (Bulletin no. 1221) issued by the Bureau of Labor Statistics of the United States Department of Labor which analyzes the provisions of 300 collectively bargained plans as they existed in the latter part of 1955.

The committee of the A. M. A. considered the information in the detailed 87-page Department of Labor report of sufficient interest to physicians and medical societies to summarize its contents and to report on various highlights of the findings. The 300 plans which were selected for inclusion in the study by the Bureau of Labor Statistics are described as broadly representative, covering groups of employees ranging from 1,000 to half a million. The plans embraced almost 5 million workers, or over 40% of the total number of employees estimated to be covered by health and insurance plans under collective bargaining at the time of the survey. The number of dependents covered by these plans are estimated by the committee to be equal, at least, to the number of wage earners enrolled in these plans.

The types of benefits included in the study were: life insurance, accidental death and dismemberment, accident and sickness, surgical, and medical care. Sections of the report also deal with maternity and related benefits, major medical, poliomyelitis, and outpatient x-ray and laboratory expense benefits. The Summary Report has numerous tables which have been adapted from the survey of the government agency and which indicate the types of analyses and breakdowns which the original report contains. Single copies of the Summary Report are available upon request, without charge, from the Committee on Medical Care for Industrial Workers.

DR. W. W. BAUER RECEIVES SCHOOL HEALTH AWARD

The American School Health Association, at its annual meeting in St. Louis, Oct. 29, will present the William A. Howe Honor Award to Dr. W. W. Bauer, for many years' service as director of the Bureau of Health Education of the American Medical Association. According to the School Health Association, Dr. Bauer's greatest contribution has been the initiation and development of the National Conference on Physicians and Schools, a means of betterment of the health of the children and youth of America.

MEDICINE AND THE LAW

NATIONAL INTERPROFESSIONAL CODE FOR PHYSICIANS AND ATTORNEYS

Preamble

The provisions of this Code are intended as guides for physicians and attorneys in their interrelated practice in the areas covered by its provisions. They are not laws, but suggested rules of conduct for members of the two professions, subject to the principles of medical and legal ethics and the rules of law prescribed for their individual conduct.

This Code constitutes the recognition that, with the growing interrelationship of medicine and law, it is inevitable that physicians and attorneys will be drawn into steadily increasing association. It will serve its purpose if it promotes the public welfare, improves the practical working relationships of the two professions, and facilitates the administration of justice.

The National Inter-Professional Code for Physicians and Attorneys was adopted by the American Medical Association at its Annual Meeting on June 26, 1958, and by the American Bar Association at its Annual Meeting on Aug. 28, 1958.

Medical Reports

The physicians upon proper authorization should promptly furnish the attorney with a complete medical report, and should realize that delays in providing medical information may prejudice the opportunity of the patient to either settle his claim or suit, delay the trial of a case, or cause additional expense or the loss of important testimony.

The attorney should give the physician reasonable notice of the need for a report and clearly specify the medical information which he seeks.

Conferences

It is the duty of each profession to present fairly and adequately the medical information involved in legal controversies. To that end the practice of discussion in advance of the trial between the physician and the attorney is encouraged and recommended. Such discussion should be had in all instances unless it is mutually agreed that it is unnecessary.

Conferences should be held at a time and place mutually convenient to the parties. The attorney and the physician should fully disclose and discuss the medical information involved in the controversy.

Subpoena for Medical Witness

Because of conditions in a particular case or jurisdiction or because of the necessity for protecting himself or his client, the attorney is sometimes required to subpoena the physician as a witness. Although the physician should not take offense at being subpoenaed the attorney should not cause the subpoena to be issued without prior notification to the physician. The duty of the physician is the same as that of any other person to respond to judicial process.

Arrangements for Court Appearances

While it is recognized that the conduct of the business of the courts cannot depend upon the convenience of litigants, lawyers, or witnesses, arrangements can and should be made for the attendance of the physician as a witness which take into consideration the professional demands upon his time. Such arrangements contemplate reasonable notice to the physician of the intention to call him as a witness and to advise him by telephone, after the trial has commenced, of the approximate time of his required attendance. The attorney should make every effort to conserve the time of the physician.

Physician Called as Witness

The attorney and the physician should treat one another with dignity and respect in the courtroom. The physician should testify solely as to the medical facts in the case and should frankly state his medical opinion. He should never be an advocate and should realize that his testimony is intended to enlighten rather than to impress or prejudice the court or the jury.

It is improper for the attorney to abuse a medical witness or to seek to influence his medical opinion. Established rules of evidence afford ample opportunity to test the qualifications, competence, and credibility of a medical witness; and it is always improper and unnecessary for the attorney to embarrass or harass the physician.

Fees for Services of Physician Relative to Litigation

The physician is entitled to reasonable compensation for time spent in conferences, in preparation of medical reports, and in court or other appearances. These are proper and necessary items of expense in litigation involving medical questions. The amount of the physician's fee should never be contingent upon the outcome of the case or the amount of damages awarded.

Payment of Medical Fees

The attorney should do everything possible to assure payment for services rendered by the physician for himself or his client. When the physician has not been fully paid the attorney should request permission of the patient to pay the physician from any recovery which the attorney may receive in behalf of the patient.

Implementation of This Code at State and Local Levels

In the event similar action has not already been taken this Code should, in the public interest, be appropriately implemented at state and local levels for the purpose of improving the interprofessional relationship between the legal and medical professions.

Consideration and Disposition of Complaints

The public airing of any complaint or criticism by a member of one profession against the other profession or any of its members is to be deplored. Such complaints or criticism, including complaints of the violation of the principles of this Code, should be referred by the complaining doctor or lawyer through his own association to the appropriate association of the other profession; and all such complaints or criticism should be promptly and adequately processed by the association receiving them.

MEDICAL NEWS

ALABAMA

Alumni Medical Program.—The first general medical program for alumni and friends of the Alabama Medical Center will be presented by the clinical faculty of the Medical College of Alabama, Birmingham, Nov. 28-29 with the scientific sessions held at the University Hospital Auditorium. University President Frank A. Rose will open the meeting with an address followed by seminars directed by Dr. J. Henry Goode, president, Medical Alumni Association of Alabama. The clinical seminar will include presentations in surgery, obstetrics and gynecology, psychiatry, medicine, and pediatrics. The morning of Nov. 29 will be devoted to a medical and surgical conference and a clinical pathological conference. There is no registration fee and the meeting has been classified for category I credits by the Alabama Academy of General Practice.

Personal.—Howard E. Skipper, Ph.D., assistant director, Southern Research Institute, Birmingham, has been appointed a member of the National Advisory Cancer Council, Surgeon General Leroy E. Burney of the U. S. Public Health Service, has announced.

ALASKA

Alaskan Health Statistics.—Statisticians of the Metropolitan Life Insurance Company have reported that between 1947 and 1957 the recorded mortality rate in the white population of Alaska decreased from 8.7 to 4.6 per 1,000, and among the nonwhites from 15.2 to 10.7 per 1,000. The recorded death rate from tuberculosis fell more than 80% between 1947 and 1957 in both the white and nonwhite populations. Actual decreases in the death rate were from 28.8 to 4.7 per 100,000 among white persons and from 574.3 to 88.4 among nonwhites. Infant mortality also showed a downward trend. Accidents was first among the causes of death in Alaska in 1957, accounting for nearly one-fifth of the total deaths. Heart disease was a close second, and diseases of early infancy ranked third, reflecting in part the high birth rate in Alaska, the statisticians report. Cancer, and influenza and pneumonia combined, were next in rank.

CALIFORNIA

Annual Lecture to Honor Volunteer Physicians.—The second annual lecture honoring the Volunteer Medical Staff of the Sacramento County Hospital, sponsored by the Sacramento County Board of Supervisors, will be given by Fred L. Soper, director, Pan American Sanitary Bureau, Regional Office of the World Health Organization, on "The Role of the World Health Organization in Disease Eradication" at the Kit Carson Junior High School Auditorium Dec. 4, 8:30 p. m. The first lecture was given by Dr. Paul D. White last January. The Board of Supervisors plan to continue to sponsor an annual lecture in honor of volunteer physicians who contribute to the care of the medically indigent of the community.

COLORADO

Poison Control Center in Denver.—The only full-fledged Poison Control Center in Colorado is at the *Denver General Hospital, Telephone Tabor 5-1331.* This center, under the direction of Dr. Robert S. Johnson, functions on a 24-hour basis furnishing consultative service, supervision of emergency treatment, and public education concerning accidental poisoning. It has excellent toxicological laboratory facilities. The center was organized by the pediatrics department of the University of Colorado Medical Center and placed at Denver General Hospital by reason of availability of personnel, funds and facilities. The Colorado State Department of Public Health serves as liaison between the present center and local health departments, contributes financially to its operation, and works with it in educational and preventive activities. The establishment of other Poison Control Centers or Poison Information Centers in the state is contemplated.

CONNECTICUT

Dedicate Radiation Therapy Center.—The new $1,165,000 Hunter Radiation Therapy Center for research and treatment of cancer and other diseases was dedicated at the Yale–New Haven Medical Center, New Haven, Oct. 10. A two-million electron volt Van de Graaff x-ray generator, a gift of the Donner Foundation of Philadelphia, will be housed in the structure, which will serve both Grace–New Haven Community Hospital and the Yale School of Medicine. The guest speaker at the dedication was Dr. Lee E. Farr, director, Medical

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Institute of Brookhaven National Laboratory. The radiation therapy center and the tumor clinic will occupy the first two floors while the top two floors will provide laboratory space for the pediatrics and medicine departments of the Yale Medical School. The center is named in memory of the family of Robert E. Hunter, of Santa Barbara, Calif., of the Yale Class of 1911, who made a gift to Yale for the new building, which is on Davenport Avenue with connecting corridors to other hospital units. The main floor will also house waiting, examining, and dressing rooms, laboratories, and a workshop. The Tumor Clinic is on the street floor. Also housed in the building will be the Tumor Registry which has some 5,000 patients registered.

FLORIDA

New Departmental Chairman.—Dr. Richard T. Smith has been selected as professor and chairman of the department of pediatrics at the University of Florida College of Medicine in Gainesville, effective Sept. 1. Hospital facilities available to the new department include 75 pediatric beds and nursery facilities for about 2,000 deliveries a year. In addition to an active out-patient department, there is an ambulant division where mothers and their children may remain together. Applicants are now being received for pediatric internships and residencies to begin Jan. 1 and July 1, 1959. Inquiries may be addressed to the Department of Pediatrics, College of Medicine, University of Florida, Gainesville, Fla.

University News.—Grants totaling $23,000 have been awarded two units of the University of Florida's J. Hillis Miller Health Center. The Atomic Energy Committee granted the College of Medicine $15,000 and the College of Pharmacy $8,000 to purchase equipment for the instruction of medical and pharmacy students in radioisotopic tracer techniques.

INDIANA

Two New University Divisions.—Dr. Walter D. Close and Dr. A. David McKinley have been made head of two new educational divisions in the Indiana University School of Medicine. Dr. Close will be in charge of an expanded medical education program for physicians serving residencies and internships on the staffs of the university hospitals and in that capacity will serve as medical director for the Long, Coleman, and Riley hospitals at the Indiana University Medical Center. Dr. McKinley will develop and direct an audiovisual aids program, assembling material for teaching and other educational activities. In addition, Dr. McKinley will supervise the operation of the Heart Station and will resume the teaching assignments in cardiology which he had given up while serving as medical director of the hospitals.

MARYLAND

Dr. Thorn Named Pincoffs Lecturer.—The second Maurice C. Pincoffs Lecture in Internal Medicine will be given at the University of Maryland School of Medicine and College of Physicians and Surgeons by Dr. George W. Thorn, Hersey Professor of Medicine at the Peter Bent Brigham Hospital, Boston. His topic will be "Adrenal Hyperfunction—Clinical Studies." The lecture in Chemical Hall will begin at 8:30 p. m., Dec. 15. The Pincoffs lectureship in medicine was established in 1957 by the faculty in honor of Dr. Pincoffs' 35 years as professor of medicine. Funds contributed by faculty, colleagues, friends, and former students made its establishment possible.

MASSACHUSETTS

Dr. Friedkin Comes to Boston.—Morris E. Friedkin, Ph.D., associate professor of pharmacology at the Washington University School of Medicine, St. Louis, has been appointed professor and chairman of the department of pharmacology at the Tufts University School of Medicine, Boston. He will succeed Byron B. Clark, Ph.D., who has resigned after 10 years to join a midwestern pharmaceutical firm.

NEW YORK

Dr. Fenn Honored.—Wallace O. Fenn, Ph.D., professor of physiology, University of Rochester School of Medicine and Dentistry, and the only member of the school's original advisory board still serving in that capacity, was awarded the Gold Medal of the Medical Alumni Association at the organization's banquet. The medal is awarded each year to a faculty member "in recognition of his integrity, inspiring teaching, and devotion to medical students."

Society News.—The Northeastern New York Radiological Society has elected the following officers for the coming year: president, Kencil L. Mitton, Schenectady, New York; vice president, Sidney I. Etkin, Albany, New York; and secretary-treasurer, Irving Van Woert Jr., Albany, New York.

Multiple Birth Roster.—The New York City Department of Health has established a "Multiple Birth Roster," intended to be a source of information for research workers in genetics, child development, and other fields. All the identifying, demographic, and pregnancy information available on the birth certificate of each infant is punched on a tabulating card. The roster will be kept up-to-date in three respects: adoption of a child, death during the first year of life, and data fed back to the roster by the individual researcher. The roster was initiated as of Jan. 1, 1958. At a later date an evaluation will be made to determine whether its use by researchers warrants its continuation. Formal requests should be submitted to Dr. Harold Jacobziner, Assistant Commissioner for Maternal and Child Health Services, New York City Department of Health, 125 Worth St., New York 13.

New York City

Appoint Chairman for New Department.—Dr. Joseph G. Benton has been appointed chairman of the newly established department of rehabilitation medicine at the State University of New York Downstate Medical Center and director of the rehabilitation department in Kings County Hospital Center, both in Brooklyn. Dr. Benton had been associated with the Institute of Physical Medicine and Rehabilitation of the New York University–Bellevue Medical Center since 1948, and was also associate professor of clinical physical medicine and rehabilitation at New York University College of Medicine.

President's Committee Award Citation to Dr. Weeden.—The President's Committee on Employment of the Physically Handicapped has awarded a special citation to Dr. Willis M. Weeden, medical director of the New York State Workmen's Compensation Board, in appreciation of his "exceptional contributions in advancing the employment of the physically handicapped." The citation was presented to Dr. Weeden by Dr. Gerald D. Dorman, New York City, chairman of the Council Committee on Workmen's Compensation of the Medical Society of the State of New York, at the Statler Hotel during a luncheon. Dr. Weeden has been medical director of the Workmen's Compensation Board for 12 years. He is a consulting surgeon at the Elmhurst General Hospital, Queens, is on the surgical staff of the New York Hospital, and is an instructor in surgery at Cornell University Medical College.

Program for Municipal Health Research.—A "purely municipal program of medical and health research" was launched Sept. 16 by Mayor Robert F. Wagner at a meeting of more than 300 of the city's scientists, civic leaders, and medical experts. The newly inaugurated New York City Health Research Council will direct the research program. Dr. Walsh McDermott, Professor of Public Health and Preventive Medicine, Cornell University Medical College, is chairman of the council. A specially created Office of Health Research within the Health Department will administer the program, and Dr. Colin MacLeod, former chairman of the Army Epidemiology Board, will head this new unit. The city has appropriated $600,000 to underwrite the first year's work. The funds will be allocated under the guidance of the Research Council and will enable scientists in local medical schools, hospitals, universities, research institutions and city departments to carry on and intensify research work on a wide range of health and medical problems.

PENNSYLVANIA

Philadelphia

Personal.—Dr. Thomas Gucker III, assistant professor of orthopedic surgery, University of Pennsylvania School of Medicine and assistant orthopedic surgeon at Georgia Warm Springs Foundation, has been appointed physician in charge of Orthopaedic Hospital's rehabilitation center in Los Angeles.——Dr. Elmer Hess, of Erie, past-president of the American Medical Association, was guest of honor at the annual dinner meeting Oct. 16 of the medical alumni society of the University of Pennsylvania. Dr. Hess is a graduate of the University of Pennsylvania School of Medicine.

TENNESSEE

Organize Research Center in Knoxville.—A new research installation, the University of Tennessee Memorial Research Center, has begun operation on the university campus in Knoxville. Housed in a 6-million-dollar building which also contains a 384-bed general hospital, the center is being organized by Dr. Stanfield Rogers, who left the Duke University Medical Faculty at Durham, N. C., last January to assume directorship of the new installation. Dr. Rogers was assisted setting up the research laboratories by Guy Thomas Barry, Ph.D., who is working in the fields of biochemistry and microbiology. The Research Center has facilities for the use of radioactive isotopes from nearby Oak Ridge. In addition to research, this institution is working cooperatively with the Biology Division of the Oak Ridge National Laboratory in Oak Ridge. It is also working cooperatively in the training of postdoctoral fellows with the medical school of the University of Tennessee College of Medicine, in Memphis. Since the opening of the Research Center, three other scientists have been added to the staff: Dr. Amoz I. Chernoff, from Duke University School of Medicine, Dr. Bernard G. Stall, III, University of North Carolina School of Medicine, Chapel Hill, and Dr. McChesney Goodall Jr., from Duke University.

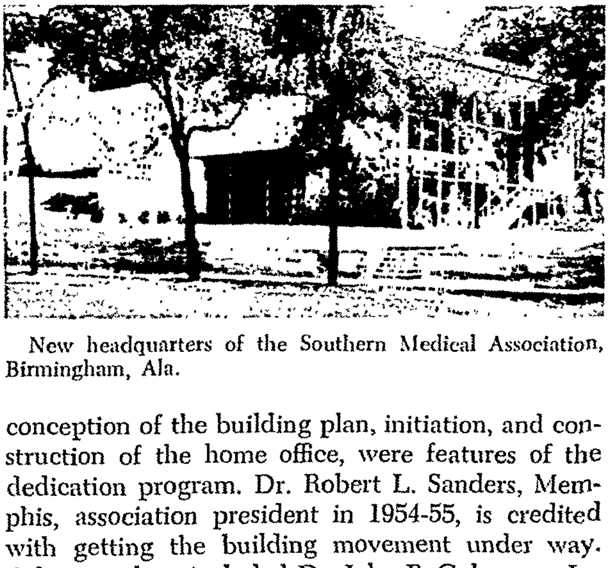
Society News.—The Tennessee Radiological Society has elected the following officers: president, 1958, Dr. David S. Carroll, Memphis; president-elect, Dr. Granville W. Hudson, Nashville; vice-president, Dr. George K. Henshall, Jr., Chattanooga; and secretary-treasurer, Dr. James J. Range, Johnson City.

TEXAS

Foreign Guest Speakers.—Baylor University College of Medicine, Houston, had Dr. John F. Loutit, director, Radiobiological Research Unit, Atomic Energy Research Establishment of Harwell, England, as its guest Oct. 31. He spoke on "Lessons in Physiology from Radiation Chimaeras." Dr. Michael G. P. Stoker of the department of pathology, Cambridge University, England, spoke before the weekly seminar of the Texas Medical Center Research Society Nov. 5 on "Studies on Growth and Latency with Herpes Virus." Dr. William H. McMenemey, of Maidavale Hospital, London, England, lectured to sophomore students Nov. 10.

GENERAL

Southern Medical Association Opens New Headquarters.—Formal opening of the new $250,000 home of the Southern Medical Association in Birmingham, Ala., Sept. 7, marked the completion of several years of planning and more than one year of construction. Association president is Dr. W. Kelly West, Oklahoma City. Remarks by past-presidents whose administrations coincided with the conception of the building plan, initiation, and construction of the home office, were features of the dedication program. Dr. Robert L. Sanders, Memphis, association president in 1954-55, is credited with getting the building movement under way. Other speakers included Dr. John P. Culpepper Jr., Hattiesburg, Miss., Dr. Lee F. Turlington, Birmingham, V. O. Foster, executive director, and Mrs. Walker L. Curtis, College Park, Ga., president of the Southern Medical Association Woman's Auxiliary. Dr. Arthur C. McCarty, past-chairman of the Southern Medical Association Council, made the official presentation of a portrait of C. P. Loranz, who has served the organization as professional relations director for 46 years and who led the building fund drive. Presiding was Dr. Milford O. Rouse, Dallas, president-elect of the association. The new building is a split-level structure fronting on Highland Avenue at 26th Street South. In addition to providing a meeting place and business center, a library-conference room, Woman's Auxiliary headquarters, and other work areas, it contains space for the monthly *Southern Medical Journal.* The Southern Medical Association, which now has 13,000 members, has maintained headquarters in Birmingham for 43 of its 52 years. It was founded in Chattanooga in 1906 and offices were in Mobile before being moved to Birmingham in 1913.



New headquarters of the Southern Medical Association, Birmingham, Ala.

Support for Undergraduate Research.—The National Science Foundation has announced plans to make grants to colleges, universities, and nonprofit research institutions to provide opportunities for qualified undergraduates majoring in the physical, biological, mathematical, and engineering sciences. About 1,000 undergraduates at some 100 institutions are expected to participate in these programs. The foundation will provide support, in accordance with prevailing campus practices, for a maximum of 400 hours per student. Details for preparing proposals may be obtained from the Special Projects in Science Education Section, National Science Foundation, Washington 25, D. C.

National Health Council Elects New Member.—The American College of Preventive Medicine has been elected to active membership in the National Health Council, bringing to 63 the number of organizations comprising the National Health Council. Its membership consists of voluntary and governmental health agencies, professional associations, civic groups, and business firms having a major interest in health. The council serves as a conference ground for these organizations to plan together for the better health of the nation. President of the American College of Preventive Medicine is Dr. Vivian A. Van Volkenburgh, assistant commissioner of the New York State Department of Health, Division of Local Health Services. Among the chief aims of the association are "the promotion and advancement of the highest possible service standards in education, practice, and research in preventive medicine and public health."

Fellowships for Women.—The American Association of University Women has announced a total of 40 fellowships for 1958-1959, open to American women who show "distinction or promise of distinction in their chosen fields of study." The two categories are (1) women who already hold the doctorate and (2) women who have fulfilled all doctorate requirements, except the dissertation. The association also offers international fellowships, $2,000 each, for which American women may apply. Both national and international fellowships are unrestricted as to field and place of study except that the international fellowships must be used in a country other than the candidates own. Candidates must have completed the residence requirements for the doctorate before the fellowship year begins

July 1, 1959. Requests for application forms must include a statement of academic status. Application deadline is Dec. 1 and successful candidates will be notified by March 1, 1959. Application forms may be obtained from Associate, AAUW Fellowship Program, 1634 Eye St., N. W., Washington 6, D. C.

Society News.—At the 15th annual meeting of the **American Medical Writers' Association** the following officers were elected to serve for 1959: president-elect, Dr. Austin E. Smith, Chicago; first vice-president, Dr. Karl A. Menninger, Topeka, Kan.; second vice-president, Dr. Theodore R. Van Dellen, Chicago; editor, Dr. Raymond C. Pogge, Cincinnati (reelected); accounting officer, Dr. Alphonse McMahon, St. Louis (reelected); and secretary-treasurer, Dr. Harold Swanberg, Quincy, Ill. (reelected).——The **American Academy of Ophthalmology and Otolaryngology**, at its annual meeting in Chicago Oct. 16, elected Dr. Dean M. Lierle, of the State University of Iowa College of Medicine, Iowa City, president-elect, to take office in January, 1960, succeeding Dr. John H. Dunnington, New York, who is now president-elect and will become president in January, 1959. The vice-presidents elected were Drs. Gordon Hoople, Syracuse, N. Y.; S. Rodman Irvine, Beverly Hills, Calif.; and Lyle M. Sellers, Dallas, Texas. The next annual meeting will also be held in Chicago.

Bahamas Medical Conference.—The sixth Bahamas Medical Conference will be held at the British Colonial Hotel, Nassau, Nov. 28-Dec. 18. Among the speakers are:

During the first week: Drs. Charles H. Brown, Cleveland; James F. Dowd, Robert Dean Woolsey, St. Louis; Edward D. Freis, Washington, D. C.; Richard A. Dunsmore, Lillian D. Dunsmore, George E. Farrar Jr., Richard F. Tislow, Philadelphia; James R. Fitzsimmons, Detroit; Alice I. Macaulay, Valhalla, N. Y.; James H. Mendel Jr., Miami; George W. Thorn, Kendall Emerson, Ross A. MacFarland, Ph.D., Boston.

During the second week: William B. Castle, Boston; Helen F. Dunbar, New York; Richard K. Greenbank, Philadelphia; Meyer Solomon, Chicago; Joseph F. Fazekas, Washington, D. C.; E. Perry McCullagh, Cleveland; I. Arthur Mirsky, Pittsburgh; John C. Saunders, Orangeborg, N. Y.; Charles Weller, Valhalla, N. Y.; Henry A. Zimmerman, Cleveland.

During the third week: Robert B. Greenblatt, Augusta, Ga.; Irving Hirshleifer, Felix Wroblewski, New York; Marvin J. Seven, Lawrence E. Meltzer, Philadelphia.

The American Medical Association is making available six films for showing at the conference. Participants and their parties enjoy special reduced hotel rates at the British Colonial Hotel in Nassau, provided that reservations are made by writing directly to "Bahamas Conferences," P. O. Box 4037, Fort Lauderdale, Fla. Reservations should be made at once. If reservations are made by telephone, call JAckson 3-7303 at Fort Lauderdale, Fla. Indicate the type of accommodation required.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

LATIN AMERICA

Dr. Leloir of Buenos Aires Receives Award.—The Helen Hay Whitney Foundation, 525 E. 68th St., New York City, announces that Dr. Luis F. Leloir, director, Instituto de Investigaciones Bioquimicas, Buenos Aires, Argentina, has been selected as the first recipient of the T. Duckett Jones Memorial Award, in recognition of his work on the isolation of uridine diphosphoglucose, and other derivatives of uridine, from plant and animal tissues. This award, which will be an annual presentation by the foundation, was made possible by the income from the T. Duckett Jones Memorial Fund, plus an equal amount from the Helen Hay Whitney Foundation, of which Dr. Jones was medical director at the time of his death. The recipients of this award ($6,500) will be chosen each year by the Scientific Advisory Committee of the foundation "for outstanding achievement in the medical field or related sciences."

CORRECTION

Preventing Blood Coagulation.—In the Question and Answer entitled "Preventing Blood Coagulation," in The Journal, Aug. 2, 1958, page 1806, it was stated that 1 mg. is equal to 10 units. This should have read 1 mg. is equal to 100 units.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Oral.* Phoenix, April 5-10. All applications already on file. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Dermatology: *Written.* Several Cities, Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *1959 Schedule—Written,* Oct. 19. Final date for filing application is May 1. *Oral.* For candidates in the South and Southwest, New Orleans, Feb. 3-6. Final date for filing application is Jan. 1. *Oral.* For candidates in the Midwest. Chicago, April 15-18. Final date for filing application is Jan. 1. *Oral.* For candidates on the West Coast. Final date for filing application is March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application is March 1. *Examination in the Subspecialties. Gastroenterology.* Philadelphia, April 17-18. Final date for filing application is Feb. 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *Part I.* Various parts of the United States and Canada, January 16. Candidates notified of their eligibility to participate in Part I must submit their case abstracts within thirty days of notification of eligibility. No candidate may take the written examination unless the case abstracts have been received in the office of the Secretary. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written,* qualifying test (Part I), Various Cities, Jan. 26. *Oral.* Philadelphia, June 3-6. Sec., Dr. Merrill J. King, 22 White St., Rockland, Maine.

American Board of Orthopaedic Surgery: *Part I.* Washington, D. C., Denver, Colorado and Rochester, Minn., Mar. 26-27. Deadline for filing application is Nov. 30. *Part II.* Chicago, Jan. 21-23, 1959. Deadline for receipt of applications was Aug. 15. Sec., Dr. Sam W. Banks, 116 South Michigan Avenue, Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Final date for filing application is February. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pediatrics: *Oral.* New York, Dec. 5-7. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation: *Written, Part I,* and *Oral, Part II.* Philadelphia, *June 12-13. Final date for filing application* is February 15. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Boston, May 9-11. Final date for submitting case reports i Jan. 1. Corresponding Secretary, Miss Estelle E. Hillerich 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Preventive Medicine: *Written. Publi Health.* Regional, Apr. 9-11. *Occupational Medicine.* Chicago, Apr. 17-19. *Aviation Medicine.* Los Angeles, Apr 24-26. Final date for filing application for all three examinations is Jan. 15. Sec., Dr. Tom F. Whayne, 343 Walnut St., Philadelphia 4.

American Board of Proctology: *Oral and Written.* Philadelphia, September. Final date for filing application i March. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garde City, N. Y.

American Board of Psychiatry and Neurology: New York City, Dec. 15-16; New Orleans, Mar. 16-17. Trainin credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services betwee the dates of Jan. 1, 1950 and Jan. 1, 1954 will be terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-11 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Regular Examination* Washington, D. C., Dec. 8-11. Final date for filing application was July 1. *Special examination in Nuclear Medicine for those diplomates in Radiology or Therapeutic Radiology.* Washington, D. C., Dec. 6. Final date for filing application was Oct. 1. *Special Examination.* Cincinnati Mar. 16-19, 1959. Final date for filing application is Nov. 1. Candidates completing training June 30, 1959 are not eligible for the Spring 1959 examinations. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: Written examinations (Part I) will be held at various centers in the United States, Canada, Hawaii, Puerto Rico, and certain military centers abroad on December 3. The date of the Fall examination in *Part I* has been changed from the last Wednesday of October as announced in its current Booklet of Information to December 3, 1958. Thereafter, examinations in Part I will be held once annually, on the first Wednesday of December. The closing date for filing applications was August 1. *Part II.* New York City, Dec. 15-16; Houston, Tex., Jan. 12-13; New Haven, Conn., Feb. 9-10; Durham, No. Car., March 9-10; San Francisco, April 13-14; Indianapolis, May 11-12; Columbus, Ohio, May 14-15. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Oral.* Los Angeles, April. Final date for filing application is Dec. 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2.

American Board of Urology: *Written Examination.* Twenty-five cities throughout the country, *Dec. 5. The oral* will be given in Chicago in February 1959. Sec., Dr. William Niles Wishard, Jr., 30 Westwood Road, Minneapolis 26.

GOVERNMENT SERVICES

NAVY

Medical Corps Retirements.—The following medical corps officers were placed on the retired list on Oct. 1, by reasons of voluntary retirement: Capt. John D. Walters, after more than 20 years active duty, and Capt. Jesse G. Wright, after more than 30 years active duty.

The following medical corps officers were placed on the retired list on Oct. 1, by reasons of reaching the statutory age of retirement: Capt. Wilbur E. Kellum, after more than 30 years active service, and Capt. Carl H. McMillan, after completing more than 30 years active service. (Captain Kellum was advanced on the retired list to the rank of Commodore.

The following medical corps officer was placed on the temporary disability retired list of the Navy on Oct. 1: Capt. Harold G. Young, after more than 31 years active service. (Captain Young will be advanced on the retired list to the rank of Rear Admiral.)

New Navy Hospital at Portsmouth, Va.—A ceremony was held Oct. 17, at the laying of the cornerstone of the new 15-story naval hospital being constructed in Portsmouth, Va. The hospital, which is expected to be completed in December, 1959, will have 800 beds, with supporting services capable of accommodating a 700-bed extension. This hospital provides the medical support for military personnel and their authorized dependents in the Norfolk-Portsmouth-Hampton Roads area of Tidewater, Va. Among other things it will have such innovations as radio-electronic paging for doctors and provisions for closed circuit television in surgical suites. The history of the Portsmouth Hospital dates back to 1830 when it was built. Today, the staff and employees of the hospital total about 1,240 persons. The new hospital will be one of the finest examples of architecture in the country. The principle address during the cornerstone laying was given by the Hon. Porter Hardy Jr., U. S. Congressman from the Second District of the state of Virginia.

VETERANS ADMINISTRATION

Personal.—Dr. Horace B. Cupp, director, VA area medical office in Atlanta, Ga., has been appointed deputy for operations of VA hospitals, outpatient clinics, and homes.

Dr. Lee H. Schlesinger, manager of the West Side VA hospital in Chicago, has been named area medical director in the Columbus, Ohio, area medical office of the VA, succeeding Dr. John G. Hood, who is being transferred to Atlanta, Ga., as area medical director.

Dr. Irvin J. Cohen, director of hospitals and clinics for VA in Washington since 1955, has been appointed to a newly created position as deputy to the assistant chief medical director for professional services in Washington, D. C.

PUBLIC HEALTH SERVICE

Increase in Grants in Mental Health Field.—A marked increase in grants to increase the supply of workers in the mental health field has been reported by Dr. Robert Felix, director, National Institutes of Mental Health. Grants to date in this fiscal year total over 16 million dollars. Grants have been made for the first time to support training of research-oriented psychologists at the doctoral level. Training emphasis will be on child development as well as physiological and social development in the human personality.

Under continuing programs to support training for mental health clinical specialists, 53 new grants were awarded this year. A total of 2,385 persons are now receiving training under these programs. They are being trained as psychiatrists, psychologists, social workers, psychiatric nurses, and public health nurses. Twelve new grants totalling $134,366 were made this year to collegiate schools of nursing to support psychiatric training, bringing the number of such schools receiving support to 71. This undergraduate program was started three years ago. Seven hundred and thirty-seven medical student stipends totaling $32,776 have been awarded. This is an increase of 313 over those awarded last fiscal year. This program, initiated in the summer of 1957, permits medical schools to offer a $600 stipend to a medical student for extracurricular clinical or research training in psychiatry.

Increased Stipends for Fellowships.—An increase in stipend rates for research fellowships has been announced by the National Science Foundation and the U. S. Public Health Service. The increased stipends, now available for future fellowships, put into effect the recommendations of senior scientists in training centers throughout the nation, said Dr. Alan T. Waterman, director of the National Science Foundation, and Dr. Leroy E. Burney, surgeon general of the Public Health Service.

The stipends from both agencies at the predoctoral level will be increased by $200. This will raise the stipend to $1,800 for the first year, $2,000 for the intermediate year, and $2,200 for the terminal year. Predoctoral allowances have been increased to permit $500 for each dependent. The new stipends for both agencies at the postdoctoral level will be $4,500 for the first year and $5,000 for the second year. In addition, postdoctoral allowances have been increased to provide $500 for each dependent. Other allowances for certain travel expenses and research supplies will remain unchanged.

DEATHS

Alter, Samuel, Philadelphia; Jefferson Medical College of Philadelphia, 1925; an associate member of the American Medical Association; member of the American Academy of General Practice; veteran of World War II; died in the Veterans Administration Hospital Sept. 23, aged 59.

Anderson, John F., New Brunswick, N. J.; born in Fredericksburg, Va., March 14, 1871; University of Virginia School of Medicine, Charlottesville, 1896; an associate member of the American Medical Association, serving as a member of the House of Delegates in 1916 and chairman of the Section on Pharmacology and Therapeutics in 1913-1914; in 1914 elected a member of the Council on Pharmacy and Chemistry of the American Medical Association; a past-president of the American Association of Pathologists and Bacteriologists and the American Public Health Association; past-vice-president of the Society for Experimental Pathology; in 1938-1939 president of the American Drug Manufacturers Association; member of the Association of American Physicians; member of the U. S. Pharmacopoeia conventions, served twice as vice-president, and also as a member of the Revision Committee; assisted the committee with the last three revisions of the U. S. Pharmacopoeia; entered the U. S. Marine Hospital Service as assistant surgeon in March, 1898; served at Ellis Island in the inspection of immigrants; was detailed as sanitary observer in Oporto-Spain, Liverpool, England, and Glasgow, Scotland; then became sanitary attache to United States consulates in Barcelona, Spain, Marseilles, France, Vienna, Austria, London and Liverpool, England; in 1901, became affiliated with the Hygienic Laboratory, U. S. Public Health Service, becoming its director in 1909, and served until 1915; resigned to become director of the Research and Biological Laboratories of E. R. Squibb & Sons, becoming a member of the board of directors in 1917 and vice-president in 1919, holding these positions until his retirement in 1946; in 1956, made a gift to his alma mater to establish a lectureship to be known as the John F. Anderson Memorial Lectures in Medicine; author of many published papers on phases of public health; served as director of the Greater New Brunswick Chamber of Commerce and vice-president of the New Brunswick Savings Institution; died in St. Peter's General Hospital Sept. 29, aged 87, of heart disease.

Boone, Henry H. Ⓜ Chicago; Chicago Medical School, 1919; died Sept. 30, aged 74, of chronic myocarditis and arteriosclerosis.

Bunker, Charles Waite Orville Ⓜ Rear Admiral, U. S. Navy, retired, Bethesda, Md.; born in Viroqua, Iowa in 1882; Cornell University Medical College, New York City, 1905; appointed assistant surgeon in the medical corps of the Navy Sept. 21, 1907, attained the grade of Rear Admiral, June 23, 1942; served in 1914 with the Fleet Marine Force during the Mexican Campaign, and during World War I with the Atlantic Transport Service, and the U. S. Naval Aviation Forces in Italy; in 1919 became executive officer of the Naval Hospital at Brest, France; in 1920 served as an instructor at the Naval Medical School, Washington, D. C.; left for Turkey in 1923 to serve on the staff of the U. S. High Commissioner there; became head of the bureau of medicine and surgery's planning division in 1931; was commanding officer of the Naval Hospital, Brooklyn, of the Naval Medical School and the National Naval Medical Center, Bethesda, Md., where he served until retired in July, 1944; was awarded various medals; service member of the American Medical Association; fellow of the American College of Surgeons; died Sept. 17, aged 76, of arteriosclerotic heart disease, myxedema, and cirrhosis of the liver.

Carter, Lew Arthur, O'Neill, Neb.; Kansas City (Mo.) Hahnemann Medical College, 1903; past-president of the Holt County Medical Society; past-president of the board of education; served as an examining surgeon for the U. S. Bureau of Pensions; formerly city physician and member of the board of insanity of Holt County; served as chairman of the Holt County American Red Cross; on the staff of St. Anthony Hospital, where he died Sept. 4, aged 82, of dilatation of the heart.

Cattermole, George Stephenson Ⓜ Denver; University of Colorado School of Medicine, Denver, 1926; a member of the staff of St. Luke's Hospital; died Sept. 8, aged 58, of coronary artery disease.

Chobot, Robert Ⓜ New York City; Columbia University College of Physicians and Surgeons, New York City, 1924; associate clinical professor of pediatrics at the New York University Post-Graduate Medical School; specialist certified by the American Board of Internal Medicine; member of the American Academy of Allergy; fellow of the American College of Physicians; past-president of the Society for the Study of Asthma and Allied Conditions; on the staffs of the University and Roosevelt hospitals; died in London, England, Sept. 26, aged 57, of coronary thrombosis.

Ⓜ Indicates Member of the American Medical Association.

Coletta, John Joseph Ⓜ Columbus, Ohio; Hahnemann Medical College and Hospital of Philadelphia, 1934; on the staffs of the Mercy and Grant hospitals; died Sept. 22, aged 50, of acute coronary occlusion.

Collins, Joseph Kennard Ⓜ Falmouth, Mass.; Boston University School of Medicine, 1952; certified by the National Board of Medical Examiners; member of the American Academy of General Practice; served a residency at the Taunton (Mass.) State Hospital; died in the Peter Bent Brigham Hospital, Boston, Sept. 7, aged 37.

Combs, Victor Ray, Phoenix, Ariz.; Hospital College of Medicine, Louisville, 1905; veteran of World War I; died in the Veterans Administration Hospital Aug. 29, aged 80.

Cornell, Beaumont Sandfield Ⓜ Huntington, Ind.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1916; L.R.C.P., of London, and M.R.C.S., of England, 1930; specialist certified by the American Board of Internal Medicine; formerly practiced in Fort Wayne, Ind., where he was on the staff of the Fort Wayne State School and member of staff of the Lutheran Hospital; editor emeritus of *The American Journal of Digestive Diseases;* died in the Huntington County Hospital Sept. 16, aged 66, of coronary occlusion.

Denman, Morris Aquila Ⓜ Livingston Manor, N. Y.; Northwestern University Medical School, Chicago, 1932; certified by the National Board of Medical Examiners; served as president-elect of the Sullivan County Medical Society; associated with Liberty-Loomis and Liberty Maimonides hospitals in Liberty; formerly Rockland town health officer; school physician; died Sept. 5, aged 54, of coronary thrombosis.

Dungay, Neil Stanley, Northfield, Minn.; University of Minnesota Medical School, Minneapolis, 1925; an associate member of the American Medical Association; fellow of the American Public Health Association; for many years associated with the faculty of Carleton College; served on the staff of the Northfield City Hospital, where he died Sept. 19, aged 75, of cerebral hemorrhage.

Eilers, Paul Gerhard, La Mesa, Calif.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1900; veteran of World War I; formerly associated with the Indian Service; died in the U. S. Naval Hospital, San Diego, Sept. 13, aged 80, of cancer.

Estabrook, Bert U. Ⓜ Detroit; Detroit College of Medicine, 1903; deputy health commissioner for 25 years, retiring in 1947; at one time on the faculty of his alma mater; died in the Harper Hospital Sept. 15, aged 78.

Exter, Donald John Ⓜ Pasadena, Calif.; University of Southern California School of Medicine, Los Angeles, 1943; fellow of the American College of Surgeons; specialist certified by the American Board of Surgery; on the staffs of the Alta Vista and Collis P. and Howard Huntington Memorial hospitals; died Sept. 20, aged 39, of a self-inflicted bullet wound.

Fellers, Ray Leopold Ⓜ Detroit; Detroit College of Medicine and Surgery, 1915; member of the American Academy of General Practice and the Association of Military Surgeons of the United States; on the staffs of the Mount Carmel Mercy Hospital and Providence Hospital, where he died Sept. 12, aged 71, of pulmonary thrombosis.

Flynn, Edward Anthony Ⓜ Belleville, N. J.; University of Vermont College of Medicine, Burlington, 1915; veteran of World War I; associated with St. Vincent's Hospital, where he was past-president of the medical staff and St. James Hospital in Montclair; affiliated with Presbyterian Hospital in Newark and St. Mary's Hospital in Passaic; chief of gastroenterology on the staff of St. Michael's Hospital in Newark, where he died Sept. 28, aged 65, of injuries received in an automobile accident Sept. 19.

Gancher, Jacob Isaac Ⓜ Waterbury, Conn.; Long Island College Hospital, Brooklyn, 1906; member of the American Academy of General Practice; a member of the original staff of St. Mary's Hospital; died in the Waterbury Hospital Sept. 16, aged 74.

Haines, Willits Parker, Ocean City, N. J.; Jefferson Medical College of Philadelphia, 1897; past-president of the Medical Society of Cape May County; served as acting assistant surgeon in the U. S. Public Health Service; a member of the honorary staff at Shore Memorial Hospital, Somers Point; died Sept. 11, aged 85.

Hall, James Frank Ⓜ Colonel, U. S. Army, retired, Washington, D. C.; Harvard Medical School, Boston, 1899; service member of the American Medical Association; fellow of the American College of Surgeons; entered the regular Army in 1901 and retired Sept. 30, 1933; died in the Walter Reed Army Hospital Sept. 2, aged 84.

Harper, Stephen F., Ashland City, Tenn.; University of Nashville Medical Department, 1910; died in the Baptist Hospital, Nashville, Sept. 19, aged 73, of myocardial infarction.

Holland, Robert E. Lee, Dallas, Texas; University of Vermont College of Medicine, Burlington, 1895; at one time associated with the Deaf, Dumb and Blind Institute for Colored Youths of Texas; died Sept. 9, aged 93.

Hood, Arthur James Ⓜ Elko, Nevada; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; past-president of the Elko County Medical Society; on the staff of the Elko General Hospital; died Sept. 19, aged 78, of chronic renal failure.

Jackson, Albert F., Nutley, N. J.; Columbia University College of Physicians and Surgeons, New York City, 1905; for many years school physician; director and vice-president of the Bank of Nutley; on the staffs of the Mountainside Hospital in Montclair, Presbyterian Hospital in Newark, and the Passaic (N. J.) General Hospital, where he died Sept. 11, aged 79, of coronary thrombosis.

Jewel, Robert Theodore Ⓜ Los Angeles; State University of Iowa College of Medicine, Iowa City, 1892; died in the Good Samaritan Hospital Sept. 13, aged 93, of acute coronary thrombosis.

Jones, Lemuel Winfield, Waco, Texas; (licensed in Texas under the Act of 1907); served on the staffs of the Hillcrest Memorial and Providence hospitals; died Sept. 1, aged 92.

Kleiner, Blanche F. Ⓜ Philadelphia; Imperial University of St. Petersburg, Russia, 1919; died in the Lankenau Hospital Sept. 18, aged 69.

Kusnitz, Morris Jr. Ⓜ Alamo, Ga.; Emory University School of Medicine, Atlanta, 1936; died in the Macon (Ga.) Hospital Sept. 7, aged 51, of cerebral hemorrhage.

Loeb, Herbert Ⓜ North Attleboro, Mass.; Julius-Maximilians-Universität Medizinische Fakultät, Wurzburg, Bavaria, Germany, 1931; on the staff of the Sturdy Memorial Hospital in Attleboro; died Aug. 12, aged 56, of coronary thrombosis.

McMahon, Ralph James Ⓜ Binghamton, N. Y.; University of Buffalo School of Medicine, 1921; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; president of the Broome County Medical Society; past-president of the Binghamton Academy of Medicine; on the staffs of the Ideal Hospital in Endicott and Binghamton and Our Lady of Lourdes Memorial hospitals; died Sept. 10, aged 60, of coronary thrombosis.

Meddis, Victor Newcomb Ⓜ Colonel, U. S. Army, retired, San Antonio, Texas; Hospital College of Medicine, Louisville, 1902; service member of the American Medical Association; fellow of the American College of Surgeons; entered the medical corps of the U. S. Army in 1920; retired July 31, 1943; died in the Brooke Army Hospital Aug. 31, aged 79, of cancer of the pancreas.

Munson, Alban Elliott, Nyack, N. Y.; University and Bellevue Hospital Medical College, New York City, 1899; an associate member of the American Medical Association; surgeon, New York Central Railroad; for many years on the staff of the Union Hospital in New York City, where he was trustee; died in the Cottage Hospital, Santa Barbara, Calif., Sept. 22, aged 84, of cerebral hemorrhage.

Nixon, Edwin Allen Ⓜ Seattle; State University of Iowa College of Medicine, Iowa City, 1928; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; past-president of the Seattle Surgical Society; on the staffs of the Columbus, Doctors, Swedish, and Providence hospitals; died Sept. 6, aged 61.

O'Connor, Clarence Joseph, New York City; Fordham University School of Medicine, New York City, 1921; also a lawyer; member of the Medical Society of the State of New York; past-president of the Bronx County Medical Society; served for many years as an honorary police surgeon; a founder and past-president of the Catholic Physicians Guild; a member of the American Board of Legal Medicine; president of the medical board and chief of medicine of Union Hospital; died Sept. 17, aged 61, of cerebral hemorrhage.

Olkon, David Mortimer Ⓜ Los Angeles; born in Wilna, Russia, Sept. 15, 1877; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; associate professor of psychiatry emeritus at his alma mater; specialist certified by the American Board of Psychiatry and Neurology; member of the American Academy of Neurology, Scientific Reserve Society of America, and Sigma Xi; fellow of the American Psychiatric Association; veteran of World War I; attending psychiatrist at the Cedars of Lebanon Hospital; at one time practiced in Chicago; served as director of the Los Angeles Neurological Institute; died Jan. 29, aged 80, of cancer of the prostate.

Owens, Frank Joseph, St. Paul; University of Minnesota Medical School, Minneapolis, 1955; served an internship at the Ancker Hospital in St. Paul and a residency at the University of Minnesota Hospital and Veterans Administration Hospital in Minneapolis; died Sept. 4, aged 28.

Percy, Nelson Mortimer Ⓜ Chicago; born in Dexter, Iowa, Nov. 7, 1875; Rush Medical College, Chicago, 1899; professor of clinical surgery at the University of Illinois College of Medicine from 1920 to 1940, when he was named professor emeritus; member of the founders group of the American Board of Surgery, and of the American Surgical Association and the International Society of Surgeons; fellow of the American College of Surgeons; past-president of the American Goiter Association which in 1953 gave him its meritorious award; past-president of the Chicago Surgical Society; in 1917 organized U. S. Base Hospital 11 in France and served as its surgical director; a life member of the Chicago Historical Society, Art Institute, and the Natural Historical Society; joint author with Dr. Albert J. Ochsner of "Clinical Surgery" published in four editions, the first in 1912; developed the Percy method of whole blood transfusion; in 1951 the Nelson M. Percy Research Foundation was organized at the Augustana Hospital, where he became chief surgeon in 1925, chief of staff in 1935, serving until 1957, when he became emeritus chief of staff, and where he died Oct. 10, aged 82, of congestive heart disease.

Phillipsen, John Albert Ⓜ Wellington, Kan.; Northwestern Medical College, St. Joseph, Mo., 1894; for many years county coroner; on the staffs of the Hatcher and St. Luke's hospitals; died June 28, aged 86, of cancer.

Phillips, John William, Oilton, Okla.; Gate City Medical College, Texarkana, Ark., 1906; for 10 years mayor; for many years on the staff of the Cushing Municipal (Okla.) Hospital, where he died Sept. 11, aged 89, of intestinal obstruction.

Quaife, Lawrence Albert, Rosalia, Wash.; State University of Iowa College of Medicine, Iowa City, 1906; served as medical director for the Chicago and Milwaukee Railroad; died in Spokane, Sept. 6, aged 79, of cerebral hemorrhage.

Rittenhouse, Jacob S., Lorane, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1885; associated with the Community General Hospital in Reading; died Sept. 4, aged 97, of arteriosclerosis.

Ross, Rex Roy Ⓜ San Antonio, Texas; born in Newton, Mass., in 1888; Medical Department of Tulane University of Louisiana, New Orleans, 1912; veteran of World War I; specialist certified by the American Board of Urology; member of the American Urological Association; fellow of the American College of Surgeons; past-president of the Bexar County Medical Society; associated with the Woodmen of the World Memorial Hospital; consulting chief urologist at the Robert B. Green Memorial Hospital; on the staffs of the Santa Rosa Hospital and the Nix Memorial Hospital, where he died Aug. 12, aged 70, of cerebral hemorrhage and arteriosclerosis.

Reeves, Alfred Edwin, North Platte, Neb.; Ensworth Medical College, St. Joseph, Mo., 1904; an associate member of the American Medical Association; veteran of World War I; on the staffs of Memorial Hospital and St. Mary Hospital, where he died Sept. 1, aged 77, of pneumonia, and chronic myocarditis.

Rinker, George Earnest Ⓜ Oto, Iowa; Sioux City (Iowa) College of Medicine, 1903; served as mayor, member of the town council, and president of the board of education; died in Sioux City Sept. 16, aged 81.

Rodenheiser, Edwin William, Upper Darby, Pa.; Washington University School of Medicine, St. Louis, 1913; specialist certified by the American Board of Pediatrics; an associate member of the American Medical Association; member of the American Academy of Pediatrics; fellow of the American College of Physicians; for many years on the staff of the Delaware County Hospital in Drexel Hill; consultant pediatrician at the Misericordia Hospital in Philadelphia, Thomas M. Fitzgerald Mercy Hospital in Darby, and Chester (Pa.) Hospital; on the courtesy staff, the Bryn Mawr (Pa.) Hospital, where he died Sept. 24, aged 67, of hypertensive cardiovascular disease.

Scott, William Wylie Ⓜ Orlando, Fla.; Medical Department of Grant University, Chattanooga, Tenn., 1907; University of Worster Medical Department, Cleveland, 1909; formerly practiced in Canton, Ohio; member of the Ohio State Medical Association; past-president of the Canton Academy of Medicine and past-treasurer of the Stark County (Ohio) Medical Society; died Sept. 7, aged 77, of cerebral vascular accidents.

Seligman, Hans Ⓜ Groton, N. Y.; Universität Bern Medizinische Fakultät, Switzerland, 1937; formerly school physician; on the staff of the Cortland (N. Y.) Memorial Hospital; died Sept. 11, aged 46, of rheumatoid arthritis and duodenal ulcer.

Shemeley, William G. Jr., Darby, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1910; veteran of World War I; an associate member of the American Medical Association; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; died in the Hahnemann Hospital, Philadelphia, Sept. 18, aged 70, of myocardial infarction.

Simmons, Harold Leonard Jr. Ⓜ New Bedford, Mass.; Boston University School of Medicine, 1944; certified by the National Board of Medical Examiners; interned at the Boston City Hospital; served a residency at the Cambridge City Hospital in Cambridge; served in the medical reserve corps of the U. S. Army; died in the Massachusetts General Hospital, Boston, Sept. 1, aged 43.

Slack, Louise Wetherill, Silver Spring, Md.; Woman's Medical College of Pennsylvania, Philadelphia, 1937; served in the medical corps of the U. S. Naval Reserve during World War II; on the staffs of the Lancaster General and St. Joseph's hospitals in Lancaster, Pa.; since 1954 employed by the department of health in Washington, D. C.; died Sept. 8, aged 50, of an overdose of barbiturates, self-administered.

Slate, John William Ⓜ High Point, N. C.; University College of Medicine, Richmond, 1900; member of the board of county commissioners for Stokes

County from 1918 to 1922; on the staff of the High Point Memorial Hospital; died Sept. 12, aged 81, of coronary disease.

Steves, Bert Jerome Ⓜ **Menomonie,** Wis.; Chicago Homeopathic Medical College, 1903; Northwestern University Medical School, Chicago, 1908; died in Fort Dodge, Iowa, Sept. 8, aged 84.

Sutton, Lyle Adin Ⓜ Albany, N. Y.; Albany Medical College, 1921; associate clinical professor of gynecology and obstetrics at his alma mater; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; veteran of World War I; chief of gynecology, Child's Hospital; on the attending staff at Memorial Hospital; consulting gynecologist at Memorial Hospital of Greene County, Catskill, and Moses–Ludington Hospital, Ticonderoga, and on the staff of the Albany Hospital, where he died Sept. 13, aged 62, of cardiac failure.

Takos, Michael James, Miami, Fla.; University of Michigan Medical School, Ann Arbor, 1951; director of research and special studies and epidemiologist for Dade County Health Department; for four years was assigned to the army's malarial control group, teaching at the school of malariology in the Panama Canal Zone; interned at the Gorgas Hospital in Ancon, C. Z., where he served a residency; received the degree of master of public health from Harvard School of Public Health in Boston; died Sept. 9, aged 39, of acute coronary occlusion.

Tetrault, Philias Eugene, Putnam, Conn.; Middlesex College of Medicine and Surgery, Cambridge, Mass., 1920; veteran of World War I; a member of the advisory board of Annhurst College in South Woodstock; died Sept. 16, aged 66.

Thomason, Charles Franklin, Whites Creek, Tenn.; Vanderbilt University School of Medicine, Nashville, 1914; veteran of World War I; died Sept. 7, aged 73, of arteriosclerosis.

Warren, Robert Franklin, Prospect Hill, N. C.; Atlanta School of Medicine, 1911; member of the Medical Society of the State of North Carolina; died in the North Carolina Memorial Hospital, Chapel Hill, Sept. 11, aged 74, of carcinoma of the lung.

Whedon, Edwin Earl Ⓜ Sheridan, Wyo.; born in Hudson, Ohio, April 29, 1872; Gross Medical College, Denver, 1902; past-president of the Wyoming State Medical Society of which he was secretary for 18 years; member of the House of Delegates of the American Medical Association in 1922 and 1930; for 15 years chairman of the Wyoming division of the American Cancer Society; past-president and for many years a member of the board of health; in 1910 city treasurer; for many years on the Rocky Mountain Medical Conference Committee; in 1954 established the Earl and Bessie Whedon Cancer Detection Fountain Center; served as Wyoming editor of the *Rocky Mountain Medical Journal*; associated with Sheridan Memorial Hospital, where he died Sept. 10, aged 86.

White, John Edward, Kerrville, Texas; Cleveland Medical College, Homeopathic, 1891; for many years associated with the Veterans Administration; formerly medical director of the Nordrach Ranch Sanitarium in Colorado Springs; veteran of World War I; died in the Sid Peterson Memorial Hospital Sept. 9, aged 87.

Williams, Charles Leroy, McMinnville, Ore.; University of Louisville (Ky.) Medical Department, 1903; at one time mayor; served on the staff of the McMinnville Hospital, where he died Sept. 8, aged 84, of pneumonia.

Williams, Hiram, Paterson, N. J.; New York University Medical College, New York City, 1896; for many years practiced in Passaic, where he was a member of the board of education; for more than 40 years examining physician for Prudential Life Insurance Company; for many years chief surgeon at Passaic General Hospital; at one time city health officer; an associate member of the American Medical Association; died in the Christian Sanatorium Wyckoff, Sept. 4, aged 89, of cerebral thrombosis

Williams, Stuart Dudley Ⓜ Richmond, Va.; Medical College of Virginia, Richmond, 1917; service member of the American Medical Association; veteran of World War I; associated with the Veterans Administration Hospital; died Sept. 13, aged 65, of acute coronary insufficiency.

Willson, William Herbert Ⓜ Greenfield, Ohio Medical College of Ohio, Cincinnati, 1897; veteran of the Spanish–American War; served as a member of the county board of health; associated with the Greenfield Municipal Hospital, where he died Sept. 7, aged 84, of cerebral hemorrhage and injuries received in an automobile accident.

Winchell, George D., Rose, N. Y.; University of Buffalo School of Medicine, 1893; an associate member of the American Medical Association; for many years county coroner; died Sept. 22, aged 96, of coronary thrombosis.

CORRECTION

Dr. Arthur Kirby Baldwin Is Not Dead.—THE JOURNAL for Nov. 1, page 1250, erroneously reported the death of Dr. Arthur Kirby Baldwin. Dr. Baldwin is still living at Carrollton, Ill., and he was named by the Illinois State Medical Society in May as "General Practitioner for 1958." The source of our information was the *News Letter* of the American Society of Anesthesiologists for September.

FOREIGN LETTERS

BRAZIL

Sinusitis.—Drs. Raphael da Nova and Décio Mion (*Revista do Hospital das Clinicas*, vol. 13, July-August, 1958) analyzed 1,593 cases of chronic sinusitis and concluded that conservative therapy gave the best immediate results. Conservative treatment was applied in 53 cases of chronic maxillary sinusitis classified as purulent, allergic, and puruloallergic. The purulent group was treated locally with streptokinase and streptodornase combined with tetracycline by mouth. The second category was treated with hormones and antibiotics. Chronic sinusitis is predominantly maxillary, and an allergic factor is important in its cause. Surgical treatment has become less popular since the appearance of antibiotics.

Prevention of Leprosy.—Fernandez and Nelson Souza Campos have stated that leprosy can be prevented by the use of BCG vaccine. In order to investigate this point of view, Dr. A. C. Pereira at the Medical School of Juiz de Fora, Minas Gerais, studied the children of leprous parents and children withdrawn from a focus of leprosy (these children having been admitted to a preventorium). From the time his study began, in 1943, he made tuberculin and lepromin tests on all the children. From 1950 on he began to give BCG vaccine by mouth for periods of one, three, and six months to obtain a complete reversal of the lepromin test from negative to positive. In an eight-year follow-up such tests remained positive. As about 33% of those with negative tests had been permanenty discharged, it was concluded that vaccination by BCG is an effective preventive of leprosy.

CANADA

Gastroenteritis.—A group of workers from Montreal and another from Kingston, Ont., emphasized the important role of coliform organisms in epidemic diarrhea in infants. The Montreal group (*Canad. M. A. J.* 79:351, 1958) isolated a new serotype (already incriminated in outbreaks in the United States), known as O127:B 8, and identified it as the cause of an epidemic in a children's hospital. Of 796 infants who were in hospital with diarrhea during a 10-month period, 258 were harboring this strain. Of these, 187 were infected in the hospital while under treatment for other conditions. Premature and newborn infants were very susceptible. Strains were at first sensitive to neomycin, but later showed emergence of resistance. Nitrofurantoin proved to be the therapeutic agent of choice. There were 28 deaths. Autopsy findings were nonspecific (intestinal congestion and hemorrhage). The serotype described is widespread in the province of Quebec. The Kingston group recorded a series of hospital infections over a five-year period and found a wide range of serological types of Escherichia coli. They encountered one epidemic with the O11:B4 type, but the proportion of E. coli infections among infants admitted with diarrhea was somewhat less than in the Montreal series. They found that giving polymyxin B by mouth was effective in shortening the duration and diminishing the severity of the infection and favored giving prophylactic doses to staff and patients in the presence of an epidemic. They urged, as did the Montreal workers, that in any epidemic of infantile diarrhea investigation for types of E. coli be carried out, with reduction in infectivity of all positive cases by neomycin or polymyxin B. Visiting must be restricted and a routine survey of all contacts for coliform organisms must be carried out. Moreover, when epidemics are present in the district, the screening of all admissions for carriers should be carried out.

Antibiotic Disks.—The Biologics Control Laboratories of the Canadian government complained last year of the poor quality of antibiotic disks coming into Canada and tightened up their control of these diagnostic products. They invited manufacturers (practically all from the United States) to cooperate by sending in samples and protocols of assay of disks. In a recent paper (*Canad. M. A. J.* 79:383, 1958) they reviewed the results of this voluntary control system, in which four manufacturers (not representing all who could have cooperated) sent in samples for checking over a year. The results showed a great improvement during this period. The problem has apparently been that manufacturers relied solely on performance tests for controlling their products, whereas the Canadian testers have developed an assay method using an extraction technique for obtaining the antibiotic from the disk. In one cooperating company, the rejection rate for low potency dropped from 15% to zero within a few months, and for another firm the rate dropped from 75 to 15%. Nevertheless, the program is being continued, and the government is considering more

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

effective regulations for the import of disks, noting that the authorities in the United States are also considering this problem.

Tetanus Toxoid.—The Academy of Medicine, London, Ontario, has had a committee studying the question of extensive tetanus immunization among the population for some time and has published a report on its findings (*Canad. M. A. J.* 79:410, 1958). It urges every physician to use his opportunities to increase the number of persons in the community immunized with tetanus toxoid and emphasizes once more that a full course of toxoid immunization must include four primary immunizing doses of which the recall dose 6 to 12 months after the first series is one. Booster doses every five years are recommended. Antitoxin must also be used when indicated. Local groups are encouraged to participate in a research plan to obtain accurate information about the incidence of allergic reactions to tetanus antitoxin in previousy immunized persons and others. Attempts will be made to promote mass immunization by the press, television, and other media and by encouraging immunization of students. The emergency departments of hospitals should give toxoid to patients if possible (but not in the same syringe as antitoxin). The provincial departments of health are requested to assume responsibility for an adequate recording system, which is at present lacking.

Insurance Plan and Public Health.—Two medical administrators in the federal government discussed the new hospital insurance and diagnostic services setup at the annual meeting of the Canadian Public Health Association (*Canad. J. Pub. Health* 49:317, 1958). Cameron discussed the general administrative systems being developed to operate provincial health insurance programs. There were some differences among the provinces, some establishing their program within the provincial health department, while others had organized a special commission with a single commissioner or board of commissioners reporting to the provincial legislature through the Minister of Health or some other responsible minister. Almost all provincial health insurance plans had developed some form of rate board to review and approve hospital budgets and establish rates for services provided. Provinces will report their expenditures under the program each month to the federal government, which will make monthly payments to the province as an advance on money due at the end of that year. A good program of research and statistics is being developed, and it is hoped that soon each province will have a punch card system for every hospital admission showing accounting data, diagnostic information, use of hospital services, and possibly basic social data on the patient.

Charron referred to the integration and coordination of preventive and curative medical activities within the hospital insurance and diagnostic services program. The fact that the Minister of National Health and Welfare is responsible for hospital insurance will make such integration easier. One area where problems will arise is that of national health grants to provinces. A joint administrative section had been set up to serve both health insurance and health grants and thus avoid duplication. The consultant services at Ottawa in various fields of public health, such as nutrition or child and maternal health, will be available for consultation in health insurance matters. As an illustration of the need for coordinated and continued health care, Charron cited the care of children. The hospital would have to work in conjunction with community public health services to assure continuity of treatment. In such areas, he believed that the development of services under the insurance plan would help to close the traditional gap existing between preventive and therapeutic medicine. Development of outpatient diagnostic services would also require consultation between public health workers and hospital laboratory workers to avoid duplication and maintain high standards. Similarly, rehabilitation and home care services would require constant cooperation.

Brachial and Digital Blood Pressure.—At the University of Manitoba, Gaskell and Krisman (*Canad. J. Biochem.* 36:883, 1958) developed an auscultatory technique for measuring the digital blood pressure. They use a stethoscope in which the diaphragm has been replaced by a digital plethysmograph, into which a finger is sealed. The technique is similar to the usual one for measuring brachial blood pressure, sounds being heard through the stethoscope as a pneumatic cuff around the finger base is deflated. The first sound heard appears to be as reliable an index of systolic pressure as any other. By using this technique in combination with the usual one, the authors were able to study the brachial to digital systolic and diastolic pressure gradients in normal subjects and hypertensive patients under various conditions. This gradient is small when the subject is cool but much increased when he is heated. The gradient in essential hypertension was similar to the normal gradient for diastolic pressures but greater for systolic pressures.

Maternal Mortality.—A recent report (*Ontario Department of Health*, Special Report no. 5) presented some data on trends in maternal mortality in Ontario between 1921 and 1955. The trend in maternal mortality followed that displayed in other countries and other areas. In 1921 the maternal mortality rate in Ontario was 5.22 per 1,000 live births. By 1931 it was still unchanged, but in 1938 it began to diminish sharply. By 1941 it had fallen to 3.03 and continued to fall until it had reached 0.54. The current hazard of childbirth in Ontario is therefore only one-tenth of what it was before 1938. Infant mortality showed a similar though not so sharp decline. These curves were accompanied by a fall in the actual live birth rate up to the time of World War II with a sharp rise afterwards to a figure just above that for 1921. An interesting feature of these statistics was the calculation by the statisticians of "lost years of reproductive life" by taking an arbitrary upper limit of 50 years and calculating how many years were lost to the population by maternal deaths before this age. These calculations show that between 1935 and 1955 the annual number of reproductive years lost was cut by 80%. In other terms, a total of 4,900 years was saved for reproduction by the dramatic and sustained fall in mortality. In line with findings elsewhere, the chief cause of fall in maternal mortality was the fall in incidence of infection. Infection has been replaced by toxemia as the first ranking cause of maternal death, though the rate for toxemia has also fallen.

Patients and Parking.—Parking in the downtown area of Saskatoon is just as difficult as in most American cities. Patients visiting their doctors often receive parking tickets, but in future the police will be more lenient with them. The Board of Police Commissioners has approved the recommendation that notes signed by physicians and dentists for their patients who receive parking tickets will be acceptable at the police station in cancellation of the ticket. Forms will have to be signed by the physician or dentist in person. Nurses and receptionists will have no authority to sign the notes. If the courtesy is abused it will cease.

Alcoholism.—The Ontario Alcoholism Research Foundation reviewed once more the figures for alcohol use and alcoholism in Ontario. The foundation now estimates that, in the decade from 1946 to 1955, the number of alcoholics increased from 31,820 to 63,070, a jump of 98.2%. Even allowing for population growth in the age groups affected, this represents an increase in the adult rate of 65.2%. In terms of the estimated number of actual users of alcoholic beverages, it represents an increase of 55.2%. During the survey period, the percentage of the Ontario population using alcohol increased from 65 to 71% and the average per capita consumption from 1.28 to 1.69 gallons. In this period, consumption of wine slightly decreased while consumption of beer and of spirits increased. The rate of alcoholism for Ontario was slightly above average for Canada, lower than that for British Columbia, slightly lower than that of Quebec, and much lower than that of the United States.

GERMANY

Operating Time. — R. Nissen (*Deutsche med. Wchnschr.* 83:1765, 1958) related the historical development of surgical technique and the duration of operation at various periods. Thus, in the preanesthetic era, time-saving operative technique was a necessity. Since the introduction of anesthesia and asepsis, however, the discussion of the speed of operating has not ceased. Kocher, Halsted, and Cushing deliberately sacrificed speed to the needs of careful tissue handling and hemostasis. Perhaps a mistake was made in generalizing their teachings, which in certain situations and for certain operations, such as those on the brain, were valid. Even today there are far-reaching differences in operative techniques between North America and European surgeons. To relate the progress in American surgery to a further development of Halsted's principles is an exaggeration. Similarly the emphasis on speed at all cost may result in dangerous neglect of careful handling. A number of tried and reliable rules make it possible to hold the length of operation to a minimum. It is pointed out that advances in modern surgery make it necessary for young surgeons to be trained in both speed and dexterity. In many operations unnecessary delay adds appreciably to the risks, e. g., operations in the elderly, combined abdominothoracic operations, and intracardiac procedures. The speed of operating should be adjusted to the general condition of the patient and the size of the operative field.

Endoscopy of the Biliary Tract.—H. Wildegans (*Deutsche med. Wchnschr.* 83:1775, 1958) said that in performing endoscopy of the biliary tract he uses a catheter (18 to 25 F.) modified by the inclusion of a lens system with an ocular, a source of light, and provision for flushing. Indications and contraindications for biliary endoscopy are the same as for common bile duct exploration. It is contraindicated in the presence of fresh signs of a preceding acute pancreatic necrosis. Visible gallstones are removed first. The endoscope is then introduced first towards the duodenum, then towards the liver under constant flushing with warm isotonic sodium chloride solution. In end-on vision the common bile duct appears as a cylindrical tube which, funnel-like, narrows towards the ampulla of Vater. The mucosa has an orange cast and contains small, red vessels arranged in a network. The ampulla has a variable appearance. Once the tip of the endoscope has gone past it, the duodenum becomes visible.

Small, movable gallstones often cause inflammatory changes in the surrounding mucosa. The removal of concretions, especially of obstructing stones in the ampulla or clumps of stones, can be accomplished under direct vision through the endoscope. Endoscopy is useful in the differential diagnosis of diseases of the biliary tract. The ostia of the right and left hepatic ducts are oval. If these ducts are dilated, it is often possible to look far into both lobes. Stones in a hepatic duct are clearly visible through the endoscope. This method provided a means of determining whether all concretions have been removed. Furthermore, the degree and extent of cholangitis are easily diagnosed. The author performed endoscopy during laparotomy in 151 patients with suspected disease of the biliary tract. Gallstones were seen in 94 (of which 26 had stones in the hepatic duct). Cholangitis was found in 73 patients and dilatation of the biliary tract without mechanical obstruction was seen in 45. Stenosis of the ampulla was noted in only four patients. Endoscopy does not exclude cholangiography. These procedures are complementary. If good preoperative cholecystograms are available, endoscopy is preferred to cholangiography at the time of operation.

INDIA

New Amebicide.—Sachdev and Dhupar (*J. Indian M. A.* 31:5 [Sept. 1] 1958) treated 27 patients who had amebiasis with a new drug (11,925). Patients with active diarrhea whose stools contained Endameba histolytica in the form of trophozoites or cysts were selected for the trial. Most of them were also subjected to a sigmoidoscopic examination. The material swabbed during sigmoidoscopy was examined. The patients were given two 100-mg. tablets three times a day for 10 days. Stool examination and sigmoidoscopy were done repeatedly after completion treatment for a period of six months. Symptomatic relief was obtained in all cases. The frequency of stools was reduced within 48 to 72 hours, and the stools were well formed by about the seventh day. From the 10th day on, the parasite could not be demonstrated in stools by microscopic examination, and sigmoidoscopy revealed either healed or healing ulcers. Of the 27 patients, 22 remained asymptomatic on subsequent examinations. The drug was well tolerated by all but one of the patients.

Intestinal Helminthic Infection.—Bhaduri and Arora (*Bull. Calcutta School Trop. Med.* 6:1 [Jan.] 1958) studied the incidence of intestinal helminthic infection in a mixed population of an industrial area. Stools of 290 unselected men from a total of 5,000 workers were examined. Evidence of helminthic infection was obtained in 114, or 39.3% Hookworms infection was obtained in 114, or 39.3%. Hookworms worms in 20; the rest had pinworms, Strongyloides, Hymenolopis nana, and Heterodera. Thus the hookworm rate was 23.1%, and the roundworm rate was 5.5%.

Postmalarial Splenomegaly.—R. N. Chaudhari (*Bull. Calcutta School Trop. Med.* 6:1 [Jan.] 1958) reported a series of 154 patients with postmalarial splenomegaly. These formed part of a group of 203 patients who were investigated to find the cause of their tropical splenomegaly. Besides postmalarial splenomegaly, they included 22 with cirrhosis of the liver, 11 with posthepatic splenomegaly, 7 with thalassemia, 6 with extrahepatic portal obstruction, and 3 with metabolic disorders. Almost all those with postmalarial splenomegaly came from rural areas, most being young adults; 128 were male and the rest female. They belonged to the poorer classes, being chiefly farmers or laborers. The onset was insidious, and the duration of enlargement varied from 2 to 21 years. All gave a history of fever suggestive of malaria, in the beginning. The persons with advanced cases were malnourished and cachectic; 114 had fever while in the hospital. The splenic enlargement varied between 3.5 and 10 in. below the costal margin. It was aggravated during febrile attacks and receded a little after the attack. The spleen was firm, smooth, painless, and mobile. The liver was enlarged to a variable extent in most patients, the left lobe usually being larger than the right. It was soft and smooth except in advanced cases when it was hard and irregular. Five with advanced splenomegaly had jaundice, and 7 gave a history of hematemesis or melena; 18 had ascites, 3 of whom had tuberculosis. The patients with advanced cases showed an altered albumin-globulin ratio with increased thymol turbidity.

Examination of the spleen, removed at operation or postmortem, showed that the normal appearance was lost. There was proliferation of the reticuloendothelial cells and giant cells and evidence of fibrosis. There was no evidence of malarial pigment. The liver showed a normal appearance in early cases and variable pathological changes in others which included focal necrosis, diffuse parenchymal degeneration, and fatty changes, while definite fibrotic changes were seen in terminal cases. Anemia of the orthochromic and slightly macrocytic type was seen in those with disease of long duration. Leukopenia was commonly present and thrombocytopenia in a few with advanced splenomegaly. Only two showed malarial parasites in the blood. Splenoportal venography showed dilated and tortuous splenic and portal veins, while collateral vessels were seen in very advanced cases. A barium meal showed esophageal varices in eight cases of long duration. The diagnosis was based on the history of residence in a rural area where malaria was hyperendemic, repeated attacks of malaria which were untreated or irregularly treated, progressive enlargement of the spleen more marked during the attacks and receding slightly after them, absence of jaundice or gastrointestinal bleeding except in terminal cases, leukopenia, a variable degree of anemia, little or no pathological change in the liver, no radiological evidence of portal obstruction in early cases, and negative tests for leishmaniasis.

Suppressive antimalarial therapy was found to be effective in early cases. Splenectomy was indicated in those with marked hypersplenism who did not respond to hematinics. The liver was not damaged, as revealed by a liver biopsy. Spontaneous and recurrent attacks of malaria occurred in about 50% of the patients who survived after splenectomy. Sixty were followed up for two to four years. Of these, 43 were treated medically and 17 were subjected to splenectomy. From the group not operated on, 22 with early cases were cured after suppressive antimalarial therapy for 6 to 12 months. Seven of the 14 with late cases showed a remarkable reduction in the size of the spleen, and others remained the same or became worse. Three of the seven in the terminal stage died, and the rest had recurrent attacks of hematemesis. Of the 17 who were operated on, 3 died of the operation and 2 died later. Five could not be traced, and the rest complained of progressive weakness and had irregular fever, and liver biopsy showed a much more advanced involvement of this organ as compared to the preoperative findings. Thus, malaria was the primary infection in these patients who developed reticuloendothelial hypertrophy and hypersplenism. To ascertain further the role of malaria in the causation of splenomegaly, a study was made to determine the effect of the control of malaria on the spleen rate in areas where malaria is known to be hyperendemic. The authors had examined 71 patients six years earlier. All but two showed improvement in general health; 24 had ceased to have a palpable spleen, and in 42 of the remaining 47 the enlargement was much less. The liver was also smaller than before. Thus antimalarial measures were definitely effective in reducing the size of the spleen by controlling the recurrent febrile attacks. With the control of malaria, the incidence of this condition was found to be greatly decreased.

Pulmonary Function Tests.—H. D. Singh (*J. Indian M. A.* 31:5 [Sept] 1958) determined the normal values for vital capacity, timed vital capacity (TVC), maximum breathing capacity, and maximum expiratory pressure in 25 healthy men between the ages of 40 and 62 years. These values were lower than those reported for men between the ages of 30 and 39. The vital capacity and one-second and two-second TVC values obtained here were again lower, and the maximum breathing capacity values were higher than the similar values obtained for an identical age group by western authors. This discrepancy between Indian and western subjects was observed in young adults as well. Since the maximum breathing capacity is a more reliable index of the ventilatory capacity of lungs, the study showed that pulmonary function in Indians is not inferior to that of western subjects.

Research Grants.—The Rockefeller Foundation gave seven grants to various institutions in India—more than to any other country. These grants include $58,000 to the Indian Council of Medical Research for postgraduate training fellowships for teachers in Indian medical colleges to be spread over the next three years. A grant of $45,000 was made to the Institute of Child Health Trust in Calcutta to support teaching and research in pediatrics by the purchase of equipment and supplies for the basic science departments and towards the further development of the institute's library. The foundation granted $21,000 for the development of the hospital record system at the Medical Record Library of the Christian Medical College at Vellore, and $100,000 was granted to the All-India Institute of Medical Sciences in New Delhi for teaching and research equipment. Although its plant has not yet been completed, the institute has been conducting undergraduate medical classes and a limited graduate program in orthopedic surgery since 1956. In the undergraduate program it stresses seminars and practical work by students as educational methods and emphasizes an integrated biochemical and physiological approach to medicine.

Prednisone for Tuberculosis.—P. K. Chatterjee and co-workers (*J. Indian M. A.* 31:6 [Sept. 16] 1958) gave prednisone to three men and one woman with tuberculosis who did not show radiologic improvement on specific chemotherapy alone. Two patients were acutely ill, one of them having a rapidly progressive tuberculosis of the cervical axillary and mediastinal lymph nodes with a segmental lesion in the lung. The others suffered from advanced pulmonary tuberculosis. Chemotherapy was given in either of three combinations—dihydrostreptomycin and PAS, dihydrostreptomycin and isoniazid, or PAS and isoniazid. The dose of prednisone varied from 1 to 2.5 mg. daily, given for a period of two and one-half to four months. The ages of the patients varied between 19 and 31 years. Three of the patients showed a marked improvement clinically and radiologically in the course of therapy with prednisone, and this improvement continued even after the hormone was stopped. The fourth patient had chronic nodular lesions and had relapsed three years after an apparently successful treatment with antituberculosis agents for one year. He did not respond to the combined therapy with prednisone and antituberculosis agents. None of the patients showed any side-effects with the small dosage used. The authors suggested that the anti-inflammatory action of corticosteroids may be of use in the treatment of actively ill tuberculous patients as they would control the toxicity and the rapid progress of the disease, if they are given in small doses and along with chemotherapeutic agents.

Filariasis of Scrotum.—U. S. Arora and co-workers (*Bull. Calcutta School Trop. Med.* 6:1 [Jan.] 1958) made lymphangiograms of 18 patients with chronic filarial lymphedema of the scrotum, their ages varying between 18 and 58 years and the duration of the disease varying from 6 months to 10 years. The edema was soft and piting in 13 and hard and nonpitting in 5. A 70% iodopyracet solution was injected into the lymphatics after they were made prominent by injection of patent blue-V subcutaneously and distal to the site of exploration. Roentgenograms were taken immediately and two, five, and eight minutes after injection of the dye. The lymphatics were well visualized in the 13 patients with soft edema. They were dilated and larger than normal, the dilatation being most marked in the early cases. Those with advanced disease showed saccular dilatation with sudden narrowing centrally, but in the five late cases of indurated edema, the lymphatics were poorly visualized. In the early cases, tortuosity and intercommunication of the vessels were also evident. The lymphatics showed absence of valves and retrograde flow of the fluid. The site of obstruction was on one or both sides and at or near the inguinal lymph nodes. Thus, as the condition progressed, an initial dilatation of the lymphatics occasioned by proximal obstruction was followed by sclerosis of the vessels leading to patchy filling appearance radiologically as was seen in the five patients with hard edema. The nonfunctioning of lympatics due to dilatation and later sclerosis lead to accumulation of tissue fluid rich in protein which caused hypertrophy of fibrous tissue and increase in size of the part involved.

Epidemic Encephalitis.—Sidhu and Taneja (*Indian J. Child Health* 7:9 [Sept.] 1958) stated that an epidemic of encephalitis broke out in Northern India in the summer of 1954, declining gradually by the end of September. Of those affected 80% were under the age of 5 years. Mortality was high, 50% of the deaths occurring within 48 hours of the onset. Routine laboratory investigations showed no specific abnormality, while the spinal fluid showed an increase in proteins and cells in some of the patients but no organisms. Postmortem examination showed evidence of early viral involvement, but virological studies on the paired serums, stool specimens, and autopsy material did not provide any clue. Evidence of antibodies against B3 Coxackie virus was found in six serum specimens while ECHO viruses were found in a few stools. By March of the next year 30% of the patients discharged from the hospital after the illness showed some type of neurological residuals. The authors observed such residuals in 109 survivors from a total of 231 patients who had encephalitis. Of the survivors, 73 had been discharged as cured and 36 had residuals at the time of discharge. The highest incidence of residuals was in the age group 0 to 2 years, the incidence diminishing with age.

Of the 36 patients 4 died during the follow-up period. Three of these had severe progressive paralysis agitans, and one had hemiplegia with recurrence of convulsions. Of the patients discharged with residuals, 15 were fully recovered within two months and 14 had partially recovered. The types of neurological residuals observed included paralysis agitans, upper motor neorone paralysis, facial palsy, mental defects, emotional disturbances, cerebellar dysfunction, choreoathetoid movements, generalized tonic spasms and rigidity, blindness, irritability, crying attacks, petit mal, aphasia, and neuritic pain. Upper motor neurone paralysis was seen in 13 and paralysis agitans in 12. Complete mental deterioration was present in four and irritability and emotional disturbances in nine. Patients with mental defects showed associated residuals such as paralysis agitans, blindness, and upper motor neurone paralysis. At the end of the follow-up period, 14 of the 29 patients still had some neurological defects. None of the extrapyramidal type of residuals persisted, these patients either dying or recovering fully. In 7 of the 13 with upper motor neurone involvement, paralysis persisted, but the commonest residual noted was mental retardation, present in 12. Irritability, present in nine at the time of discharge, disappeared in all, but emotional disturbances were still present in two. Of the patients discharged originally as cured, six had some postencephalitic sequelas. Lumbar pneumoencephalography done in patients with residuals showed positive evidence of cortical atrophy in 11.

UNITED KINGDOM

Physical Activity, Fat Intake, and Blood Coagulation.—McDonald and Fullerton (*Lancet* 2:600, 1958) showed that the coagulability of blood, measured by the recalcified plasma clotting time (R. C. P.), increases after the ingestion of animal fat in the form of bacon, butter, and eggs and also after the ingestion of such vegetable fat as margarine. The increasing mortality from coronary artery disease has followed changes in vegetable fat intake more closely than the alteration in animal fat consumption. The authors also considered that the increased mortality from coronary disease runs parallel with the general decline in physical exercise, which has taken place owing to the increase in mechanization of industry and transportation. Consideration of these facts led them to examine the effect of physical activity on the increase in blood coagulability which follows the ingestion of a fatty meal.

After their R. C. P. time had been estimated, 16 healthy men were given a meal containing 85 Gm. of animal fat and the estimation repeated after three and one-half hours, during which they were comparatively inactive. On another day the same type of meal was taken, but the subjects walked for six miles before the R. C. P. was estimated. During the inactive period the mean difference between the fasting R. C. P. and that found three and one-half hours after the meal was 23.8 seconds. After the six-mile walk the corresponding figure was 7.3 seconds. In another test the authors found that animal and vegetable fats in equal amounts produced about the same increase in blood coagulability. The hypothesis that the incidence of coronary disease is related to a low level of physical activity accords with these findings. If shortening of the R. C. P. can be regarded as indicating a greater tendency to fibrin formation in vivo, and if intravascular fibrin formation is the important factor leading to atheroma, it follows that any factor which operates over long periods, and which can be shown to shorten the R. C. P., is likely to be causally related to the development of atheroma. Two such factors are a high fat intake and a low level of physical activity.

Minamata Disease.—An unusual neurological disorder caused by eating contaminated fish, known as minamata disease, was described by McAlpine and Araki (*Lancet* 2:629, 1958). The disease takes its name from a small industrial town near the southwest coast of Kyushu, Japan. The effluent from a large artificial fertilizer factory empties into Minamata Bay. A mysterious nervous illness recently began to affect villagers near the bay, assuming epidemic proportions within two years, and causing death in more than a third of the victims and serious disability in most of the survivors. Concurrently, a fatal illness affected domestic animals, scavenging crows, and fish in a nearby bay. It was established that eating fish was associated with the occurrence of the disease and that fish responsible for the outbreak were caught in Minamata Bay. Chemical analysis of silt from the bay suggested that the water was polluted by effluent from the fertilizer factory. No fresh case has been reported since fishing in the bay was banned. The onset of numbness in the limbs and around the mouth of those affected suggested peripheral nerve involvement. In a few patients the numbness became generalized and was accompanied by sensory ataxia. Cerebellar symptoms were conspicuous at the onset, and pyramidal signs were sometimes observed. Not infrequently there was deafness and disturbance of vision, with constriction of the visual fields. In the more seriously ill patients there were mental confusion, stupor, coma, convulsions, involuntary movements, and insomnia. In some the presence of intellectual deterioration, mutism, epilepsy of late onset, limb spasticity, and incontinence suggested a form of progressive neuronal degeneration. Some of the neurological features of Minamata disease have been observed in toxic states due to certain metals, particularly thallium. It is conceivable that this is in the factory effluent, which is still being examined.

Acute Respiratory Disease in the Royal Air Force.—Acute respiratory disease in military personnel is a serious problem, since not only is time lost in training, but a substantial number are invalided with serious lung damage. Respiratory infections are serious in air crew because of the effect on the middle ear at high altitudes. McDonald and coworkers showed that in the Royal Air Force the incidence of acute respiratory infection is highest in the recruit units (*Brit. M. J.* 2:721, 1958). The major cause of invaliding in the R. A. F. for respiratory disease is illness contracted at recruit camps. Time spent at these stations represents at most 8.3% of the total service, whereas about 67% of all illness leading to this type of medical discharge is acquired during this period. The adenoviruses and influenza account for at least 50% of the illnesses during the severe and protracted winter epidemics in recruit stations. In nonrecruit units, as in the adult civilian population, the adenoviruses do not appear to be a frequent cause of illness. Although many outbreaks are due to influenza virus, the cause of a relatively high proportion of acute respiratory disease requiring hospitalization is unknown. Influenza A virus accounted for about 12% of the patients admited. Adenovirus infection probably spreads rapidly under the conditions in a recruit camp, with its quick turnover of young men drawn from all parts of the country. More than 50% of those invalided from the R. A. F. with a respiratory disease, other than tuberculosis or cancer, were discharged as a result of an acute respiratory disease contracted in their recruit training period.

CORRESPONDENCE

AID FOR PHYSICIANS

To the Editor:—In the year 1849 the South Carolina Legislature passed an act creating "The Society for the Relief of the Families of Deceased, Disabled and Indigent members of the Medical Profession of South Carolina." The purpose of this society as stated in the act of incorporation is as follows:

"And be it further enacted by the authority aforesaid, that the principal end of the said corporation shall be, to succor and maintain, and relieve the families of deceased and disabled indigent members of the Medical Profession of the State of South Carolina, members thereof, in such manner, and according to such rules and regulations as they may see fit to establish."

For 109 years, except for the years of the war between the states, this small group of physicians have contributed from their meager funds a "bounty" to wives and children of less fortunate colleagues. I would appreciate information concerning other such organizations that may be in existence in this country. It is believed that the South Carolina society is the oldest in America. It would be interesting to know if this is true. It has been learned that there are so-called benevolent organizations of this character in New York, New Jersey, Massachusetts, and California. I would be grateful if I could be furnished a list of such society's with the addresses of all of the officers. It would be interesting to compare policies and experiences.

ANTIPYRETIC EFFECTIVENESS OF ASPIRIN AND SALICYLAMIDE

To the Editor:—A paper comparing the antipyretic effectiveness of aspirin and salicylamide was published in The Journal (167:1821-1826 [Aug. 9] 1958). The authors throughout the article appear to concede the superiority of aspirin as an antipyretic in pediatrics, but their conclusions would seem to favor a new proprietary preparation. It seems advisable to call attention to several faults in the article.

In the selection of patients for this study, 19% of the patients were under 6 months old, 46% were from 6 to 12 months, 27% were from 1 to 2 years, and only 8% were from 2 to 3 years of age. In view of the recognized instability of the temperature-regulating mechanism in infants under 2 years of age, the findings as a whole lose validity. A proper and more informative choice would have been a higher age group in young children where the fever vagaries encountered in infants could be avoided

In a similar connection, there was an unfortunate selection of a base-line temperature of 100.2-101.0 F (37.9-38.3 C) rectally, which in such young infants is inconsequential and in many instances is quickly remedied without medication. Had there been chosen, as a base, a minimum temperature of 102 F (38.9 C), as was done by Colgan and Mintz (*J. Pediatrics* 50:552-555 [May] 1957), the tests would have possessed much more significance and the authors' own findings would have demonstrated the superiority of aspirin as an antipyretic to even a greater extent. Moreover, a clear and precise definition of what the authors actually viewed as antipyresis would make the data more valuable.

It also seems advisable to comment on the dosage of the drugs administered to the test patients. The investigators used 2 grains per year of age of salicylamide and 1 grain of aspirin, only one-half this dosage, in spite of the fact that the generally accepted dosage for both these agents is equivalent (Sollmann, *A Manual of Pharmacology*, ed. 8, Philadelphia, W. B. Saunders Company, p. 742-743). Yet, the report reads in part, "The data seemed to indicate that aspirin could produce greater drops in temperature and control pyrexia of a higher degree than could salicylamide. . . ." In the summary all reference to the self-evident superiority of aspirin is omitted.

The authors have also expressed some opinions on the relative toxicity of salicylamide and aspirin, based on published literature. For example, they quote references to the effect that the LD$_{50}$ of salicylamide is double that of aspirin, implying that it is twice as safe. One of these references reports no original determination of the LD$_{50}$ of salicylamide at all but merely refers to several other papers. The results in these papers, as well as of more recent references, do not confirm the contention that the acute toxicity of salicylamide will be half that of aspirin in humans. What they do show is that it is unjustified to assume that there is any essential difference between the two drugs. The wisest position in this regard is that taken by New and Nonofficial Drugs, 1958, p. 306, which states that "the toxicity of salicylamide compares closely with other salicylates. . . ."

A more questionable viewpoint is expressed when the authors imply that the LD$_{50}$ of salicylamide in mice, without consideration of species variation, or he slope of the dosage mortality curve, can be readily projected to children to prove the extent of ts safety. Such crude estimates, based on rodent data only, are frequently unjustified and may lead to serious errors in the evaluation of toxicity.

Convenience of administration and patient acceptability are evidently the principal reasons why these investigators lean toward the salicylamide preparation. But it is obvious from their paper (and the dosages administered, 32, 64, 128, and 192 mg.) that they used a dosage form of aspirin other than children's aspirin, which is palatable and certainly acceptable to infants and young children as demonstrated by its widespread use. Since it is in 1.25-grain tablets, it is convenient for accurate administration. Nor does it have any of the grittiness complained of in the paper in question.

EVALUATION OF DRUGS

To the Editor:—The article, "Factors Influencing Clinical Evaluation of Drugs," by Modell and Houde, in The Journal (167:2190-2199 [Aug. 30] 1958) was most interesting and important. However, a most significant factor in the appraisal of drugs should be mentioned in this connection, and that is timing. By timing, I am referring to the time of the year or season in which the test or study is being made, as it pertains to certain drugs. Specifically, let me refer to the hay fever remedies for which glowing reports are made each year in advance of the peak times of pollination. During seasons of comparatively low pollen counts, previous to these peaks, yet regarded as the hay fever seasons, the antihistamines, ephedrine, and even the steroids are extolled in the most glowing terms. But, when the heights of the pollen seasons arrive, symptoms of hay fever and asthma occur in numerous patients and in many with a severity as great as if these drugs had not been used. The point is that the results claimed for the drugs were based on wrong timing. The studies should have included the peak of the pollen seasons.

In 1938 Bloom (*J. A. M. A.* 111:2281-2283 [Dec. 17] 1938) reported excellent results in hay fever with potassium chloride; this remedy was rapidly taken up throughout the world and was even regarded by some as a "cure." However, when I clinically tested a large group, at the crucial time, potassium chloride proved a failure and has since practically disappeared in hay fever therapy. Another example was ascorbic acid. Most drug stores had posters prominently displaying the virtues of vitamin C for allergy. A similar study disproved its value when administered at the peak time (Engelsher, *J. A. M. A.* 126:318 [Sept. 30] 1944). Timing, therefore, is a most important point in appraising drugs, especially those used for hay fever.

ISONIAZID TOXICITY

To the Editor:—I wish to comment on Dr. Ross' article entitled "Use of Pyridoxine Hydrochloride to Prevent Isoniazid Toxicity" (J. A. M. A. 168:273-275 [Sept. 20] 1958). Contrary to what Dr. Ross concludes, I believe it is fair to assume that the issue of whether or not pyridoxine, which is at least in part transformed into pyridoxal in vivo, interferes with the antimicrobial action of isoniazid is settled. It does interfere. Not only has this phenomenon been observed in vivo in mice by McCune et al, but also we have observed a small but difinite antagonistic effect some time ago in performing microbiological assay studies for isoniazid in serum from patients given pyridoxine with isoniazid.

However, what Dr. Ross failed to emphasize—and I think it is most important—is the quantitative side of this phenomenon. Simple arithmetic calculations from the data presented by McCune will reveal that it took enormous doses of pyridoxine to antagonize isoniazid's chemotherapeutic activity, on a weight for weight basis; indeed, the proportion of pyridoxine to isoniazid used in McCune's studies is more than 100-fold greater than the proportion which has been shown to be clinically effective in preventing peripheral neuritis. It is so much greater that Dr. Ross' statement that "it appears wise to use isoniazid without pyridoxine in the routine treatment of tuberculous patients in clinical practice," seems unjustified.

Finally, in view of the many reports and publications concerning the wide variation in rates of metabolic inactivation of isoniazid among different patients, it seems surprising not to see reference in the article to the point of view which we expressed some time ago (Carlson, H. B., and others, *New England J. Med.* 255:118-122 [July 19] 1956), namely, that those patients (some are certainly encountered in the routine treatment of tuberculosis in clinical practice) who metabolize isoniazid so rapidly that standard dosages of this drug may not be therapeutically adequate, should receive pyridoxine when the indicated dosage of isoniazid is higher than 5 mg. per kilogram of body weight per day.

MISCELLANY

MISSILES OR PENSIONS

Louis M. Orr, M.D., Orlando, Fla.

If you have ever watched a film of a rocket ascension, you will notice that the rocket starts out slowly and somewhat unsteadily, building up speed as it rises. It is during this first, slow acceleration that the flight can be cancelled by adverse winds and the rocket grounded.

There is a parallel with our nation's present venture into deficit financing. Each year our budget is a little higher, a little broader. Each year the federal government gets a little deeper into more programs which should be locally organized and administered. For part of each year the United States government, the government of the richest nation on earth, lives from hand to mouth, with only enough money in its treasury to pay next month's expenses.

Almost every year, Congress debates raising the statutory debt limit.

But this is only the beginning of the rocket's flight. Each new federal program starts out small—but each program not only grows itself but also gives birth to further programs.

Soon we will pass the point at which adverse pressure can slow or turn the flight—and then the rocket will really take off!

Our country has gotten so big that we tend to forget that we're supposed to be running it. Most of the time what goes on in Washington seems so far away from us that we either lose track or treat the Washington news like it doesn't concern us.

I expect my patients to take an interest in their treatment—after all, it's their health that will primarily be affected. And I feel very strongly that every taxpayer should take a personal interest in the actions of his government. After all, it's our incomes they're operating on.

I'm sure most of you have, at one time or another, run into the notion that doctors should stick to medicine—and leave running the country to the self-styled "experts." Well, strictly within my own field of competence, I know that it is unhealthy for a man to keep living beyond his physical means. No man can go on, year after year, getting less sleep than he needs, less food than he needs, without serious deficiencies. Psychologically, too, as a doctor, I know that it is unhealthy for a man to live in a state of constant debt, spending more than he is making. If he worries about his debts constantly, the strain is bound to affect him. And if he doesn't worry about his debts, that's even worse.

Our government is living beyond its economic means; it has already accumulated a good deal of excess fat in the form of programs which either should not be government responsibilities at all or should be handled at the local level. Even if my voice is not heard as a taxpayer, as a physician I say this is an unhealthy state for our nation to be in.

I am not going to try to cover all the economies possible in our federal government. Instead I am going to talk about the savings possible in just one agency of the government—the Veterans' Administration. And how much could be saved by merely taking the VA out of programs which are really not its proper field? In the next 40 years we could save over 80 billion dollars.

As you are well aware, medicine is intimately involved in welfare programs. You might say that we have a vested interest. This welfare may be as simple as the giving of a relief check to a man because he's too sick to work or it may include full hospital and medical assistance. Federal agencies acknowledge medical care as an integral part of welfare—so much so that medical care programs for the indigent now receive special support and encouragement. So the medical profession has an interest, a very special interest, in federal welfare spending—a professional interest, in addition to our interest, as taxpayers, in how our money is spent.

The medical profession views with a particularly jaundiced eye the constantly increasing federal intervention into the private lives of our citizens. We must be free to practice our art and science to the limit of our own ability—not to a set of rules and regulations compiled in Washington. This is why the medical profession keeps a constant and watchful eye on federal spending in the health and medical care fields.

I happen to be chairman of the American Medical Association's Committee on Federal Medical Services, a committee of the Council on Medical Service. This committee is only one of several A. M. A. departments which keep track of new developments in federal medicine.

In recent years, we have found the Veterans' Administration welfare and medical program to be one of our greatest causes for anxiety. For the past five years, the American Medical Association, the state associations, and the individual physicians have been saying, "It is time to call a halt, time to consider where we are heading—and whether we really want to go there."

This is one of the programs on which we must set a brake—now, while it may still be possible—before it takes off into outer space.

Why are we so concerned with this one agency? Surely, we physicians would not deny that our nation's veterans have a right to our help? We are concerned for a number of very serious reasons:

Vice-Speaker, A. M. A. House of Delegates.

Read before the 15th Annual Meeting of the Delegates and Assembly of the Association of American Physicians and Surgeons, April 10, 11, 12, 1958, San Francisco.

First, the VA's programs provide federal aid directly to individual citizens. Most federal aid programs work through the states, such as Public Assistance or Hill-Burton—they are grants-in-aid, funds to help the state carry out a program. But the state has no voice in the VA's operations, nor has the county or the community.

This program short-circuits the whole American system of local control and local responsibility for the individual's needs. It is a prime example of direct central government, which the people can control only through Congress and the President.

In the absence of local control, confusion results. A good example is in the administration of the Hill-Burton program, through which the federal government makes grants to the states to help in the construction of local hospitals.

When submitting plans for proposed hospitals a state is required to estimate the number of citizens, including veterans, that the new hospital will serve. On the other hand, when counting the number of existing beds in the state, they are not allowed to include those beds in VA hospitals.

So, the veterans get counted twice—once to determine where VA beds are most needed and once to determine where Hill-Burton beds are most needed.

We believe that such confusion and duplication could be eliminated if government programs were under local control where we can see what's going on.

Second, the VA is turning many of our veterans into government wards. It saps their initiative by giving them the soft cushion of federal money to fall back on, and decreases the community's feeling of responsibility for its own members.

The medical profession is not accusing all veterans, or even large numbers of them, of dishonesty or malingering.

It is true, however, that there are men, who if offered free medical care or a lifetime pension, will not make any great effort to refuse it—even though they have suffered no injury from their military service to earn it.

Third, as physicians we are concerned because this program has brought into existence one of the largest chains of government-owned hospitals in the world. Anyone who has the interest of his community's hospitals at heart should be concerned. America, of all nations, knows the competitive advantage chain purchasing can give—and many a local hospital has felt the press of VA competition for medical and nursing personnel—and even for patients.

Fourth, and this should concern all taxpayers, the VA has now one of our government's largest spending programs, outside of defense costs—and it is still going up. If we do not change the program now, its cost will reach almost 5 billion dollars a year by 1960. By 1985, under present laws, it will be costing us 6 billion dollars a year—and that will keep on until the end of the century, at least.

By the year 2000 we could well have half our population paying billions of dollars in welfare benefits to the other half. We could have a federal hospital system two or three times as big as our present one, draining off medical personnel from the rest of the population.

The American taxpayer is long-suffering—but how long could the nonveteran population stand this pressure.

The enormity of our future obligations can best be seen by looking at the past. In the period immediately following World War I we had 4 million new veterans in the nation.

There were about 26,000 government hospital beds available for treating veterans with service-connected disabilities—and 9,500 of those beds were empty. What resulted?

First, the hospital beds were opened to any veteran—with or without service-connected disabilities. This benefit was cut during the Depression, but reinstated almost immediately—leaving the present situation, where a veteran who suffered no harm from his military service can get free hospital care when a bed is available—just by stating that he cannot pay for care.

Next, pensions were authorized for World War I veterans with non-service-connected disabilities rendering them unemployable, and for their survivors.

Under present laws, these pensions will eventually cost the nation over 30 billion dollars for World War I veterans. This is more than half the cost of all benefits granted these veterans—and more than the 26 billion dollars the war itself cost us.

Today, instead of some 5 million veterans—from World War I and earlier wars—we have over 22 million. Instead of 26,000 hospital beds, we have 129,000 beds—and less than 42,000 patients being treated for service-connected disabilities.

How much will our two "new wars"—World War II and Korea—cost us in veterans' benefits?

Under present laws, it is estimated that World War II will cost almost 110 billion dollars for pensions and over 123 billion dollars for other benefits; Korea will cost us 53 billion dollars in pensions and 26 billion in other benefits.

That is a total of almost 312 billion dollars for these two wars—371 billion for the veterans of World War I, World War II, and Korea. This is a debt of over $2,100 for every man, woman, and child in the United States today.

And almost 300 billion dollars of that cost is still ahead of us! These are huge figures we are dealing with. Too often their immensity is not real to the average citizen.

True, from Washington we hear talks of budgets and appropriations which soar into millions and billions of dollars. But, in our normal every day living our economic world is one of dollars, half dollars, quarters, nickles and yes, even pennies. The astronomical cost of veterans' benefits are almost as hard to grasp.

Maybe it would be easier to "get the feel" of these costs in terms of individual veterans—almost $13,000 for each of the 5 million who served during World War I, plus $14,000 for each of the 16 and a quarter million who served during World War II—and almost $15,000 for each of the five and a third million who served in the Korean conflict.

Or almost $14,000 in federal money to each of 26 and a half million men—one out of every six persons in the United States.

Do you remember the old poem about the blind men and the elephant? It used to be in almost every school reader—how one man felt the trunk and said "It's like a snake" and another felt a leg and said "It's like a tree" and another felt a side and said "It's like a wall."

Sometimes, approaching something as vast as the Veterans' Administration, I feel a little like one of those blind men. This is almost too big to see *all* at once. You have to take a view from one side—and then from another—and then from another—and *only* when you put them all together do you begin to get an idea of the whole picture.

VA costs, for instance—maybe their size will come clearer if I take just one more aspect—How big a bite do they take out of the budget each year?

In 1920, veterans' benefits were small change—by modern standards—less than 500 million dollars a year—rising gradually to 744 million in 1944.

But in 1945, as the first wave of World War II veterans hit, costs jumped to 2 billion dollars,—in 1946, to almost 4½ billion, and in 1947 to 7½ billion.

They stayed over 5 billion dollars until 1951, then dropped to a little over 4 billion in 1954.

But now the cost is on the rise again. Let me repeat—by 1960, the VA will be spending almost 5 billion dollars a year—and the cost will continue to rise to 6 billion dollars a year by 1985—and will stay close to that figure until the end of the twentieth century.

These astronomical figures are all based on the continuance of presently existing laws.

Should a general service pension be enacted for veterans of these three wars—as was enacted for veterans of earlier wars—veterans' benefits could cost us over 760 billion dollars—more than double the cost we now face.

In the face of this already frightening financial burden promised by our laws, it seems almost cruel to project additional increases—but, as a doctor, I must point out that these figures do not allow for any significant increase in the Veterans' Administration's hospital system.

Yet, unless we act now, the medical care program seems very likely to increase—and for the same reasons that the pension program will increase.

We have two great classes of veterans' benefits—the service-connected and the non-service-connected. The service-connected benefits are those intended to aid the veteran who was actually injured in some way—mentally, physically, socially—by his military service. I am including here those readjustment benefits like unemployment compensation and educational benefits which are intended to help the veteran in his initial readjustment to civilian life.

The non-service-connected benefits are those granted to the veteran who suffered no harm from his military service. It provides him with assistance in difficulties which are a common civilian hazard—like illnesses and disabilities resulting from everyday life—and which have nothing to do with his military service.

It is obvious that the greatest demand for service-connected benefits will come in the period immediately following a war. The bulk of compensation payments for service-connected disabilities will begin then, and gradually drop off as the veterans and their survivors die. The bulk of service-connected hospital care will at least begin during these years, even for the long-term cases.

But when does the demand for non-service-connected benefits show up?

As the veteran grows older—and more infirm; as he becomes less able to pay his own way; as the diseases of age catch up with him.

That is why the VA's costs are beginning to rise. Today pensions cost nearly half as much as compensation; by 1965 they will exceed compensation—and by 1985 pensions will cost over three and a half billion dollars—more than all other VA costs put together—and the case-load will include three *and a half million veterans and veterans'* survivors.

This change can have its effect on VA hospitals, too.

Today, almost two-thirds of the VA's patients are being treated for non-service-connected disabilities. Every applicant on the VA's waiting list wants treatment for a non-service-connected condition.

In January, 1956, there were 20,000 applicants waiting—in January, 1957, 22,000—and in January, 1958, 24,000. And not one a service-connected disability.

Can you see the pressure mounting for more VA hospital beds as this waiting list mounts? As our World War II veterans become older and begin to suffer the ravages of time—which affect non-veterans as well—can you see Congress being besieged with demands for "more VA beds for my State"—or your state—or yours?

Every last man of our 22 million veterans is eligible for VA hospital care, if he needs it, as soon as he signs the statement that he is unable to pay. The only limiting factor left is the number of beds empty.

How many veterans are going to find it easier and easier to sign that statement as they get older—and more frequently sick?

We have already built 80,000 hospital beds whose obvious purpose is to provide more "available beds" for the non-service-connected ill. We have no legal ceiling on the size of the VA hospital system.

How long, with this mounting pressure from the states, will the VA stay its present size?

How can we save this country from the mounting costs of veterans' benefits? Very simple:

First—apply realistic standards to the compensation program;

Second—even if we do not eliminate pensions, at least make them supplementary to instead of duplicating the income maintenance programs for the whole nation;

Third—return the VA hospital system to the job it was set up to do—the care of service-connected disabilities.

I have no quarrel with the idea behind the compensation program—the veteran who is disabled as a result of his military service is entitled to compensation for that disability. However, the disability rating and award program, as it stands, is unrealistic and full of inequities.

For example, there are men drawing 10% and 20% disability checks monthly for life who are disabled only nominally—actually, they are holding down full-time jobs. If these cases were settled on a lump-sum basis, the annual compensation load would be decreased over 300 million dollars per year.

There are veterans whose compensation is based on a legislative presumption of service-connection—rather than evidence. There are veterans receiving statutory awards for a particular type of disability, which results in their receiving more compensation than a man who is rated as more severely disabled. There are members of veterans' families receiving survivor benefits who were not actually dependent on him—and survivor benefits are provided through eight different federal programs.

Fifty-seven per cent of the compensation cases are in the 10 and 20% disability category. Adoption of lump sum payments, revision of the rating schedule to reflect actual service-connected disability and coordination of the overlapping and duplicative survivor benefit programs—plus the obvious savings in administrative overhead—could save some 9 billion dollars in the next forty years.

The greatest savings can be made, however, through revising the pension program—and it should be emphasized again that pensions are payments for non-service-connected disabilities. They have nothing to do with military service—except that veterans can get them and nonveterans can't.

Further, these vast costs will be doubled—to over 700 billion dollars—if general service pensions should be enacted.

How do we avoid this huge cost? Simply by making the pension system, as the Bradley Commission suggested, "a reserve line of economic defense" for the needy veteran or his survivors—until their needs are met through OASDI or other available sources of regular income.

You see, the situation has changed vastly since the Twenties, and not only in the size of the veteran population. Then, a needy veteran had few resources except special pensions. Today, the Old Age, Survivors, and Disability Insurance (OASDI) program covers more than 80 per cent of the men over 20—and veterans receive social security wage credit for time spent in uniform. In 20 years, almost all veterans will be covered.

In addition, there are now other federal retirement programs, industrial retirement plans, insurance programs covering medical care, disability and retirement. Pensions are no longer the only source of funds for the needy veteran.

In fact, a 1955 survey showed that almost half the over-65 VA pensioners were also receiving OASDI benefits. The veterans without dependents averaged $550 a year from OASDI; those with dependents averaged $659.

By coordinating VA and OASDI payments, and setting the total payment to a veteran at a level consistent with need standards set by local governments—we can reduce pension costs by over 70 million dollars annually for those over 65.

When we take into consideration the fact that OASDI benefits are now available from the age of 50 for the totally disabled, this coordination could save about 158 million dollars a year.

By carrying this coordination and revision of the payment schedule over to the survivor pension program—and paying these pensions only to those who need them—we could make an additional immediate saving of over 80 million dollars a year.

The pension load is increasing—and will continue increasing to the end of the century. With the anticipated case-loads, adoption of these suggestions would cut pension costs 68 billion dollars during the next 40 years. With the savings on the compensation program, we could save a total of 77 billion.

If this reappraisal—and revision—staved off the calamitous specter of a general service pension, we would save almost 250 billion dollars. This is almost as much as the present total federal debt.

And, of course, these estimates are only—only—*until the end of this century.*

Survivor benefits are still being paid to over five thousand dependents of Civil War veterans; the last survivor benefit for the War of 1812 was paid in 1946—131 years after the war ended.

How much would be saved by cutting down on VA hospitalization and returning the care of non-service-connected disabilities to local responsibility?

The Hoover Commission, in 1955, listed a number of hospitals which it found to be surplus to the VA's operations—even continuing non-service-connected care. Removing these hospitals from the federal expense account would save some 7½ million dollars a year. Limiting care provided to service-connected cases would, according to the Commission, save another 150 million dollars per year.

It is my personal opinion that this is probably a great understatement of the savings that could be made in this program. Just to give one indication—the VA itself reports that inpatient care at its hospital cost 624 million dollars in 1956—and that only 36% of the daily load was service-connected. Gradual elimination of the two-thirds of the patient load which is non-service-connected would be more likely to result in a saving of almost 400 million dollars; or 16 billion in 40 years.

However, even keeping to the Hoover Commission estimates, we could save 6 billion dollars more by returning the VA hospitals to the service-connected patient.

These three changes—in compensation, in pensions, in hospitalization—would, then, result in a saving of about 83 billion dollars in the next 40 years. How much more it would save by keeping off our backs new pension programs, more VA hospital beds, more federal control of medicine, and more federal intervention in local responsibilities is impossible to estimate.

I have chosen only three of the VA's programs to exemplify the savings possible in this agency—but I would like to try to give you some indication of what a colossus it really is. The blind man has talked about the trunk and the leg of the elephant—but the elephant has other features as well.

Here's just a brief run-down: The VA, in 1956, provided out-patient care for over two million veterans; provided domiciliary care for an average of 17,000 veterans daily; did research into tranquilizers, blood diseases, cancer; distributed and did research in prosthetic appliances, provided vocational rehabilitation training for half a million veterans; received 600,000 applications for loan guarantees; acted as guardian for 348,000 beneficiaries; helped support the Philippine Veterans Memorial Hospital in Manila; and insured almost 6 million veterans under NSLI and USGLI policies.

The VA employed over 176,000, including 146,000 in its medical programs, and spent over five and a half billion dollars. It had 2,300 residents—almost 1,400 in general surgery and internal medicine.

I know I am beginning to sound like the World Almanac—and I don't expect any of you to memorize all the facts and figures which have been wheeling around your head for the past half hour.

I do hope I have left you with some idea of how huge the Veterans' Administration—which should be concerned primarily with the needs of some three million veterans with service-connected disabilities—has become. Medical research programs, residency training, free hospitalization for all veterans, pensions for unemployable veterans, insurance, guardianship, atomic research, loans—that's an awfully large number of pies to have fingers in!

It should be obvious, I believe, that we have abdicated much of our local responsibility to this one government agency. The question is—when will it stop?

Where do we go from here? I see, and I hope I am right—the American people rising up and taking over the United States government again, putting it back on the rails—and out of all the places it doesn't belong.

As a taxpayer, I say we should stop and reconsider before we are bankrupt. As a doctor, I say we should stop before this unhealthy condition turns into an incurable illness. As an American, I say we should stop before we spend away our liberties—either by the federal government buying them from the states—or by not leaving enough cash in the account to pay for defense against our enemies across the ocean.

The rocket has almost reached the stratosphere. The time to stop it is now before the ascension becomes unstoppable—short of an explosion. It can be done—but not without your help.

BUSINESS PRACTICE

This is the sixth in a series of excerpts from the brochure on the Business Side of Medical Practice, prepared by the American Medical Association in cooperation with the Sears-Roebuck Foundation.

WHAT INSURANCE SHOULD A DOCTOR CARRY?

Insurance is of vital importance to you, especially so if you are in private practice. Articles on the subject appear frequently in many of your professional journals. How to protect yourself from the various hazards inherent in the practice of medicine is a matter which should receive thorough consideration.

Insurance is a broad subject and has many ramifications—far too many to try to cover them all here. This summary treatment is included primarily to call these matters to your attention and to provide a basis upon which to plan your insurance program in light of your personal and professional circumstances.

Property and liability insurance should be looked upon as protection rather than as an investment. It is designed primarily as a means of safeguarding against financial loss, and, as such, it performs a vital function in our economy.

Insurance should provide for self protection, employee protection, and the protection of the family. Self-protection insurance can be divided roughly into the following classifications: protection against liability; protection against loss caused by fire and theft; and protection against loss of or lowering of income due to disability caused by sickness or accident.

Liability

Generally, liability may be of two types. One may result from the actual practice of medicine (professional liability), and the other may rise by virtue of owning or leasing property, including office and ownership or operation of automobile, as well as liability which could result from personal activities which are not in any way related to the practice of medicine.

Professional Liability.—Among the significant hazards involving the medical profession are the claims and legal actions for alleged malpractice. Each year, according to some estimates, about 5,000 suits are instituted and an unknown number of claims are settled out of court. Practically every one of these incidents has its detrimental effect on the profession as a whole, undermining public confidence in the profession and sometimes in the physician himself. In the absence of such insurance protection, the doctor might be obligated to pay damages, court costs, including his attorney's fee, and many other expenses in the event a suit is decided in favor of the plaintiff. As a result, many a physician's career could well end in bankruptcy. Even though the physician is declared innocent of any malpractice, the costs incident to investigation and defense, coupled with attendant loss of earning, can be burdensome.

The mounting number of claims involving liability of all types, together with spiraling judgments, has resulted in increases in the premiums for this type of insurance. Insurance is based on averages. Premiums vary according to what the insurance companies have had to pay out in claims plus the costs of doing business. Physicians can contribute toward lowering premiums by a disciplined program of claim prevention.

The potentiality of a threatened claim or suit alleging malpractice is one of the hazards of medical practice. In view of this, every physician is well advised to be ever mindful of this and take due precautions to avoid those situations which result in poor patient-physician relationships. Although by no means complete, the following suggestions are among those mentioned most frequently by medicolegal authorities which should minimize patient-physician problems and also reduce the possibilities of suits or claims. To a large extent, these may well be helpful in defending a claim or suit should you become so involved:

1. Make a special effort to satisfy the patient during all phases of diagnosis and treatment—a new patient dissatisfied with an initial treatment tends to brood, tell others of his dissatisfaction, possibly including a lawyer.

2. If the fee for treatment might appear high to the patient, in the absence of an explanation of your services, discuss it frankly before you set it. "Surprising" fees are sometimes the springboard for malpractice accusations.

3. When in doubt about a diagnosis or alternative method of treatment, recommend that a consultant be called in. Enter this recommendation in the patient's file. In the event the patient declines your recommendation, ask him to sign a statement to that effect and keep the statements in your records. This protects two ways—it protects the doctor and leaves to the patient the responsibility for refusing consultation.

4. Do not guarantee a therapeutic result either directly or by implication. Explain the problem to the patient and the possible results. If his welfare requires a calculated risk, explain it in advance.

5. Be sure that all instructions to the nurse are completely understood. The nurse is normally con-

sidered to be the doctor's agent, and, if an error occurs in executing any instruction, you may be held responsible.

6. Remember that the telephone may be a booby-trap for both misdiagnosis and misunderstanding of instructions. Whenever possible, avoid giving a patient advice by phone.

7. Do not neglect or abandon a patient without serving reasonable notice. Whenever possible, make arrangements to have a colleague accept the responsibility of treating your patients when you are unavailable. Many physicians notify their patients in advance when they plan to be away for any length of time.

8. Familiarize yourself with your state laws concerning malpractice. Laws vary from state to state. You should also be informed regarding the limitations which specify the time within which legal action may be instituted.

9. Keep records which are accurate and up to date. If a complaint should be filed against you, never alter or destroy the records.

10. Should any incident occur which you suspect could lead to a suit or claim, you should give immediate notice to your insurance company.

11. During obstetric or similar examinations of female patients, be sure a nurse or other woman employee is present.

Professional liability insurance is available in each of the 48 states and territories. A number of constituent associations and component societies have so-called group professional liability insurance programs available to member physicians.

The limits of liability (per claim and for all claims during any one policy year) depend on many factors. Among them are type of practice—specialty or general—the economic level of the community, the claims consciousness of the people in the area and other factors.

In this matter it is best to consult your medical society and colleagues in the area. Even with the most skilled and careful physician, suits are possible and the doctor should protect himself with insurance that will take care of the expense if it should happen to him as well as to safeguard his estate in the event of an adverse judgment.

Public Liability

Any owner or leaser of property may be held legally responsible for an accident occurring on the premises which is attributable to his neglest. If a doctor leases a suite in a public building, his responsibility may be presumed to begin the minute the patient enters his office. If his office facilities include land and a parking area for patients, his responsibility may extend there also.

The incidence of such accidents is relatively low, and the physician may question the advisability of covering the possibility with insurance. The premium cost is modest, accidents do occur, especially where the public is concerned, and such coverage can save considerable financial embarrassment.

Automobile Liability.—Automobile liability is perhaps among the most commonly understood of all forms of liability protection, and it is not necessary to cover the subject here in detail, other than to recommend that the physician should carry adequate limits of coverage. It probably is better to carry too much liability rather than too little.

Also, the doctor should be aware that, if an employees uses his or her car in performing a service for the doctor and has an accident while doing so, the doctor may be sued as well as the employee. It is a simple matter to have the employee include the doctor as a coinsured in his or her policy. You should also consider coverage that will protect you while driving an automobile not owned by you such as one you may rent temporarily or one which may be lent to you. In addition to automobile liability, you will undoubtedly be interested in and wish to carry other elements of automobile insurance.

Fire, Burglary, Home, Theft, and Comprehensive Insurance

Whether fire insurance is secured for the office, the home, or both, it should include not only the building but the value of the furniture and equipment as well. The valuation is not normally based on the replacement cost but on the depreciated or actual sales value at the time. For this reason, an inventory of equipment and furniture should be kept current and in a safe place, preferably in the safe deposit box at the bank.

After a physician has been practicing for an appreciable length of time, his files, including accounts receivable, are very valuable property. Frequently these items are the least protected against fire or other loss. It is possible to carry insurance against loss of these records, but whether or not these records are insured it is recommended that they be kept in a fire-proof safe or vault when not in acutal use.

With burglary and theft insurance, the cost depends largely on the location of the office and the amount of money kept there. The amount of cash in a doctor's office may not be enough to warrant the expense of such insurance since many burglaries of doctors' offices are for narcotics rather than money. Although actual cash loss may be small the damage to the building and equipment can be substantial. A recent newspaper article describing a burglary of a doctor's office listed the loss as $5.80 worth of narcotics and an estimated damage to the furnishings and equipment of over $3,000. The loss and damage was covered by insurance. In buying this type of protection, it is well to include damage to property.

Comprehensive or "All Risk" Coverage.—Several facets of insurance incident to home ownership and operation of a professional office can frequently be consolidated. Many multiple line companies offer comprehensive policies which provide protection against a variety of hazards including fire, theft, and windstorm, as well as personal and public liability at a total premium charge which may be substantially less than the cost of the same insurance in separate policies. This is because such a blanket type of policy can be processed more cheaply by the company. It is worth considering when planning your over-all insurance program.

Accident and Health or Disability Insurance

The physician in individual practice is the sole income producer. Anything which keeps him from his practice for any appreciable length of time can be a serious financial hazard. Because of this, accident and health or disability insurance is attractive to him. Many insurance counselors consider this type of protection equally if not more essential than life insurance, since a period of disability entails support not only of the family but the disabled doctor as well. Loss of earnings may extend over months or years.

In considering this type of coverage, you should purchase it from a company which is licensed in the state and preferably through a local agent or broker. Perhaps this type of insurance is subject to more variables than other branches of insurance. Accordingly, sound advice and careful planning should prevail in arranging this phase of your insurance program.

Basically, this type of insurance is designed to replace a portion (not all) of your earned income in the event of disability due to accident or illness. Such insurance is available generally on a individual basis; and in some areas, group and franchise programs are available through professional organizations and associations.

Individually underwritten policies are of three general types: cancellable, guaranteed term, and noncancellable. The first type can be terminated by the company at any time. A guaranteed term contract is not normally subject to cancellation during any term for which a premium has been paid and accepted; however, the insurer may elect not to continue the contract on any renewal date. Noncancellable contracts are not only that but are guaranteed renewable at each premium due date up to a specified age. Fraud, or intent at fraud through misrepresentation of facts, however, may be considered as just cause for terminating a contract if resorted to, either in applying for insurance coverage or in claiming benefits.

The premium costs vary and are determined by several factors, such as type of contract (cancellable, guaranteed term, or noncancellable), amount of weekly or monthly indemnity, occupation or profession, age, sex, length of time for which benefits are payable, whether benefits are payable for nonoccupational disability or cover both occupational and nonoccupational illnesses and injuries, and the waiting period between the date of disability and the commencement of benefit payments.

All other factors being equal, premiums may be reduced considerably by selecting a policy which has a fairly long waiting period between the onset of disability and the time benefits start. Such waiting periods eliminate the necessity of paying for short periods of disability and the attendant administrative cost and conserve a correspondingly greater portion of the premium income to pay for longer periods of disability which are of more serious financial consequence.

The underwriting requirements of insurance companies differ, but most of them will not knowingly issue benefits which will approximate net earned income of the applicant.

In varying degrees physicians may, as mentioned earlier, participate in group or franchise disability insurance programs through membership in professional associations and societies. Although these programs have their merits, they may have to be utilized primarily to supplement rather than replace other coverage.

You should make sure that your health history at the time of applying for insurance is not misrepresented since most non-group contracts promise benefits only for disability resulting from accidents and illnesses that originate subsequent to the date the policy is issued.

Office Overhead Insurance.—When the doctor is incapacitated his office overhead goes on. Salaries, rent, utilities, and such must be met. To meet this contingency you may wish to consider a relatively new form of disability insurance which was designed for this specific purpose. Although underwritten like disability insurance, benefits are based on verifiable office overhead fixed expenses rather than earned income. This, as well as the cost of insurance protecting the physician against professional liability and against fire and casualty loss of office equipment and supplies, may be considered a business expense and deductible when figuring income tax. It should be noted, however, that the proceeds obtained from such insurance is considered taxable income.

Employee Insurance

Most states have statutory requirements regarding the responsibilities of an employer. Prior to the employment of another physician, a nurse, a technician, or receptionist, you would be well advised to learn fully what your responsibilities are. Workmen's compensation laws generally spell out the extent to which an employer is financially responsible for the death or disability of an employee as a result of an occupational accident or injury. Since the laws vary from state to state and their applicability often depends, to a degree, on the number of employees, you should make certain that you do not assume any hazards unnecessarily.

In some jurisdictions there is a state monopolistic fund which is the sole source of insurance for protection against workmen's compensation liability. In other states, the employer may select from a number of private carriers. The cost of the type of protection depends on several factors, but primarily upon the classification of employment and the amount of payroll.

Sources of information include the state agency which administers the law, your local medical society or state medical association, your insurance counsellor, and your attorney.

Many employers provide or make available, in addition to employee protection required by law, other forms of insurance for the benefit of their employees. These include life insurance, disability insurance, and hospitalization benefits. Some of these forms of coverage may be available as extensions of benefits offered to members of professional societies.

Life Insurance—Family Protection

Life insurance is primarily a form of protection for the doctor's family and possibly his creditors in the case of his death. Additionally, it can be a form of savings and can also be used to supplement a retirement program. The subject is so large that it could well be the subject of a special pamphlet. Although there are many different varieties of programs, the three most common types of policies are term, ordinary life and endowment, or annuity contracts.

Term insurance involves the lowest premium cost. Such contracts are usually issued on a level premium basis with coverage lasting only for the term specified. Most contracts provide that the policy holder may convert his coverage to a permanent plan of insurance, without evidence of insurability, provided such option is exercised within a prescribed period. This form of coverage is referred to frequently as "pure protection," since it does not normally include cash surrender or loan values.

Ordinary life insurance is the classification frequently given to contracts of a permanent nature, which do not usually include endowment or annuity features. Generally speaking, the policies provide for level premium payments throughout the life of the insured with the face amount becoming payable at death. There are modifications, however, whereby such coverage may be purchased on a basis that the insurance becomes "paid-up" either at a specified age or after the payment of premiums for a specified number of years. Although such policies become paid up at the designated time, the face amount is not normally payable until the death of the policy holder.

Ordinary life insurance policies usually contain guaranteed cash and loan values as well as provisions for extension of insurance for a stipulated length of time in the event premium payments are not continued. Thus, such policies contain an element of savings in addition to just insurance protection.

The third general category is known as endowment or annuity insurance. Such contracts contain both the features of insurance protection and savings. Under an endowment policy the face amount becomes due and payable at the end of the contract period. The face amount also becomes due and payable in the event the policy holder dies prior to the completion of the premium paying period. An annuity contract usually matures in the same manner as an endowment policy but, in addition, may provide for periodic payments (rather than a lump sum) to the policy holder in the form of retirement income.

There are varying combinations of the foregoing types of coverage which an individual can arrange for in his life insurance programing. Several professional organizations including constituent associations and component societies have established group and franchise plans in which physicians may participate. Life insurance planning should be done on an individual basis and the physician is well advised to utilize the services of a competent insurance counsellor. Insurance needs often change due to family and financial circumstances.

Since most permanent life insurance contracts provide for a great deal of flexibility, it may be advantageous to have your program analyzed periodically and modified, when indicated, so that it will fulfill, on a current basis, the purposes you intend.

Insurance is designed to protect you, your family, and your employees. It is an important consideration when establishing a practice, so devote enough time to it and secure advice that will enable you to develop an adequate insurance program.

MEDICAL FILM REVIEWS

This Is Nursing: 16 mm., color, sound, showing time 29 minutes. Produced in 1957 by and procurable on rental ($7.50) or purchase ($250) from Educational Film Sales Department, University Extension, University of California, Los Angeles 24.

This film demonstrates the scope of professional nursing activities in contributing to effective rehabilitation of the patient; it stresses that rehabilitation is dependent on coordination of all health workers rather than on one individual. Designed for nurses, physicians, medical students, and lay groups, it shows the teamwork needed in rehabilitation programs, with special emphasis on the nurse's role. It shows that rehabilitation takes time, professional skill, understanding, and contributions from many people, while at the same time the responsibility rests on the individual himself. Emphasis is on the team approach in dealing with the patient, and the film also shows that rehabilitation starts immediately on the patient's admission. It should make a valuable contribution for discussion purposes in nursing groups. Although they are not pictured as members of the team, dietitians and medical social workers should also be interested, since seeing the patient in the film would alert them to his problem.

NEW FILMS ADDED TO A. M. A. MOTION PICTURE LIBRARY

Helping Hands for Julie: 16 mm., black and white, sound, showing time 25 minutes. Cleared for television. Presented by the American Medical Association and the American Hospital Association. Sponsored as a public service by E. R. Squibb and Sons, Division of Olin Mathieson Chemical Corporation, New York. Produced in 1958 by Henry Strauss Productions, Inc., New York. Procurable on loan (no service charge) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10.

This film is designed to attract students to health careers by dramatizing their opportunities. The story revolves around Julie's fight for life when she is brought into the hospital emergency room—diagnosis unknown. Her family doctor, a surgeon, and a resident mobilize the entire medical team, and it swings into swift, disciplined, and decisive action. The helping hands aiding the doctors in this vital search for the correct diagnosis are those of nurses, medical technologists, x-ray technicians, and the medical record librarian. With the diagnosis made, the drugs of the pharmacist, the nourishing food of the dietitian, the restorative work of the physical therapist, and the care of the nurse help to bring Julie back to health. This is a moving story which is well told and has a powerful emotional appeal. The complexity of the modern hospital service, including the record room, visiting medical staff, internist, surgeon, pathologist, radiologist, interns and residents, medical technologists, x-ray technicians, pharmacist, dietitian, physical therapist, and nurse, is shown in the right perspective. It will appeal to high school and college students and is especially recommended for physicians who are called on to lecture to groups on health careers.

Ectopia Cordis in a Twin: 16 mm., color, sound, showing time 8 minutes. Prepared in 1957 by Elliott S. Hurwitt, M.D., and Alvin Lebendiger, M.D., New York. Produced by a grant in aid from Medical Research Division of Johnson and Johnson. Procurable on loan (service charge $1.00) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10.

Complete ectopia cordis in a live infant occurs so infrequently that few physicians are given the opportunity to observe a newborn baby whose heart is beating outside of the thoracic cage. The authors have prepared this film to document a situation that has rarely been reported: premature twin boys, one essentially normal and the other born with his heart projecting almost at a right angle to the long axis of the body. The surgical attempt to provide a covering of skin for this heart, the postoperative appearance of the baby with his heart beating subcutaneously, and the combination of major intracardiac and extracardiac abnormalities found at autopsy are illustrated and demonstrated. This case-record film presents an unusual condition. An attempt made to replace the heart in the chest proved unsuccessful. Nevertheless, the condition, although unusual, is of interest, especially to cardiologists.

Someone Is Watching: 16 mm., black and white, sound, showing time 15 minutes. Produced in 1957 by Information Productions, Inc., New York, for the New York State Department of Health. Procurable on loan (service charge $2) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10.

This motion picture calls attention to the various ways in which legal narcotics stocks fall into the hands of dope addicts and peddlers through carelessness and false confidence, and it emphasizes the need for safeguarding of drugs. Actual cases are taken from the files of the New York State Health Department's Bureau of Narcotics Control. Included among these cases are those of a registered nurse who gains a place on the hospital staff and steals from the hospital drug stocks while on duty, a repairman who gains admittance to the office of a general practitioner under the pretense of having been called to repair a sterilizer, and a confidence man working with accomplices who dupes even the wary druggist. This film is highly recommended for showing to physicians, hospital administrators, nurses, and pharmacists.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Perforation of the Heart During Cardiac Catheterization and Selective Angiocardiography. D. J. W. Escher, J. H. Shapiro, B. M. Rubinstein and others. Circulation 18:418-422 (Sept.) 1958 [New York].

The authors report on a 24-year-old woman who was admitted to Montefiore Hospital in New York for evaluation of suspected congenital heart disease. The patient underwent a standard diagnostic cardiac catheterization with the aid of a Cournand type catheter, and after its completion selective intracardiac biplane angiocardiography was performed with the aid of a 7 National Institutes of Health (NIH) catheter. Anteroposterior and left lateral projections were obtained 2 and 8 seconds after the injection of the contrast medium (50 cc. of 70% sodium acetrizoate [Urokon]) into the right ventricle; they revealed the appearance of some of the contrast medium in the pericardial cavity coincident with its anticipated appearance within the right ventricle. The amount of contrast medium in the pericardial cavity was gradually increasing to the end of the examination. Several globules of the contrast medium were seen in the right ventricular apical myocardium distal to the tip of the cardiac catheter, suggesting that perforation of the heart had occurred at this point. A portable chest roentgenogram, with the patient in the sitting position, showed the cardiac shadow to be somewhat enlarged, with contrast medium collected along the diaphragmatic surface of the pericardial cavity. The heart rate rose to 139, the blood pressure dropped to 70/40 mm. Hg, and the occurrence of cardiac tamponade seemed certain.

With the aid of general endotracheal anesthesia, the right chest was opened and the heart exposed. A vertical pericardial incision was made anterior to the right phrenic nerve, and about 200 cc. of blood-stained fluid gushed forth under tremendous pressure. The heart beat immediately became strong and full, and the peripheral pulses returned. At the apex of the right ventricle, there was a soft cleft, the point where the perforation must have occurred. There was no further bleeding. The postoperative course was uneventful. There is reason to suspect that perforation probably did not occur with the Cournand catheter which is relatively flexible and which was not inserted in the area of the apex of the right ventricle. The perforation occurred more likely during the insertion of the relatively sharp-tipped, more rigid NIH catheter, most probably when the catheter was additionally advanced after its initial positioning. The occurrence of perforation of the myocardium during cardiac catheterization with selective angiocardiography serves to emphasize some of the risks taken in the application of several of the newer, specialized methods now available for the evaluation of congenital heart disease. With careful technique and good team work, however, the danger to the patient can be held to a minimal level and is far outweighed by the positive values of the procedures.

A Study of the Manifestations of Rheumatic Fever Following Cessation of Therapy. E. E. Fischel, C. W. Frank and M. T. Bellows. Circulation 18: 367-370 (Sept.) 1958 [New York].

The authors studied the reappearance of rheumatic activity in 257 children during a 3-week observational period after cessation of treatment for acute rheumatic fever with corticotropin (ACTH), cortisone, and aspirin administered for 6 weeks in a cooperative clinical trial of these drugs in the United States and Canada. Of the 257 children, 67 (26.1%) did not show any manifestations of rheumatic activity, and the remaining 190 (73.9%) had some manifestations, most frequently an increased erythrocyte sedimentation rate or rise in temperature. Occasionally more severe and complex manifestations occurred. The number of manifestations was greater in those patients with more severe initial involvement, i. e., at the start of the 6-week therapy. In some patients the severity of the disease during the post-therapy period was as great or greater than at the institution of the treatment. In most instances, the various abnormalities subsided spontaneously. Re-treatment was considered necessary for only 6 patients.

When any or all of the presenting manifestations of rheumatic fever subside during drug therapy, the effect may be attributed to several possible causes: spontaneous remission in the course of the

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1949 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

disease, bed rest, or the drug administered. After cessation of therapy, the recurrence of rheumatic manifestations is ample evidence that the drug employed did not eradicate the disease. However, it is also evidence, in retrospect, that the drug had a suppressive action while it was being administered. It was widely thought that aspirin did not affect the rheumatic inflammation in the heart, and that concept has occasionally been extended to cortisone. The recurrence of heart failure or pericarditis after withdrawal of either drug conflicts with this view. A flare-up of the disease process could not be expected if a totally ineffective agent were withdrawn. The manifestations of the post-therapy period are sufficiently common under apparently good conditions of management. Study of the post-therapy period should be included in attempts to define optimal therapy for rheumatic fever, and it may provide some perspective concerning diagnostic criteria.

The Cardiac Complications of Hypertension. A. L. Cornish. J. Kentucky M. A. 56:862-864 (Sept.) 1958 [Louisville, Ky.].

At least 60 to 75% of hypertensive patients ultimately succumb to cardiac complications, especially heart failure. Coronary atherosclerosis has been found in 90% of patients dying with hypertension. Cardiac involvement, as a rule, does not develop until hypertension has been present for 12 to 15 years. Eventually the strain of maintaining an elevated blood pressure, plus the effect of coronary sclerosis, takes its toll on the ventricular muscle. In all probability, the effect of coronary sclerosis predominates. Later, impairment of kidney function leads to retention of salt and thus aggravates congestive heart failure. The hypertensive heart patient may present himself with either congestive heart failure or the picture of coronary insufficiency or both. Congestive heart failure develops slowly in about half of the patients and suddenly in the other half. When it is sudden, a definite precipitating cause should be searched for. Correcting the precipitating cause greatly improves the prognosis. The more common precipitating causes of acute congestive heart failure in hypertensive patients are respiratory infections, increased coronary insufficiency (silent infarction), paroxysmal tachycardia, excessive sodium intake, discontinuation of digitalis therapy, hemorrhage and anemia, development of thyrotoxicosis, pulmonary embolism, too rapid administration of blood or other sodium-containing infusions, physical and emotional strains, and uncongenial climatic conditions.

In the further management of hypertensive patients with congestive failure, the author found it useful to let the degree of functional impairment guide the treatment. In a class 1 patient, when heart disease is present but there is no symptomatic limitation of activities, he merely tries to lower the blood pressure, explains the precipitating causes of heart failure, and encourages weight reduction. If the patient is in class 2 and has symptoms on moderate exertion, periods of rest plus a slowing down and delegation of responsibility are advised. In a class 3 patient, who has symptoms on ordinary exertion, the author uses more active measures, such as careful digitalization and moderate sodium restriction. Another important manifestation of hypertensive heart disease is angina pectoris. The essential clinical feature is that the anginal pain occurs with exertion and excitement, lasts only a few minutes, and is relieved by rest and administration of glyceryl trinitrate (nitroglycerin). The electrocardiogram is diagnostic in 95% of cases, showing depression of the RS-T segment and T-wave abnormalities. If these are not present when the patient is at rest, Master's exercise test may bring them out. Factors contributing to angina pectoris must be searched for and treated—for example, anemia, hyperthyroidism, peptic ulcer, diaphragmatic hernia, gallbladder disease, and associated heart failure. Precipitating factors must be avoided. Slow walking, with rest periods, and care about exercising on a full stomach and in cold weather are advised. Nearly every obese patient benefits from losing weight. Of all drugs used for angina, glyceryl trinitrate alone has stood the test of time. A mild sedative may help the anxious patient.

Degenerative Cardiovascular Disease in the Orient: II. Hypertension. H. A. Schroeder. J. Chron. Dis. 8:312-333 (Sept.) 1958 [St. Louis].

The author studied the incidence of arterial hypertension and its serious consequences among the patients of 13 university teaching hospitals in 9 Oriental cities, namely, Taipeh (Taiwan or Formosa), Victoria (Hong Kong), Manila (Philippine Islands), Bangkok (Thailand), Agra, Lucknow, Bombay, and New Delhi (India), and Beirut (Lebanon), and in Japan. Hypertension was frequently observed among these Oriental populations, being diagnosed both clinically and pathologically. In several cities cardiologists or internists expressed the opinion that the incidence of hypertension was increasing. No conjecture can be made as to whether the apparent increase in hypertension is merely one symptom of an aging population or is related to some new environmental factor added during the past 27 years covered by the study. When measured in Oriental people, dietary intakes of sodium chloride, to which hypertension might be related, either approximated or were less than the ranges commonly accepted for Americans, with the possible exception of the northern Japanese. Therefore, it was most difficult to ascribe the frequency of hypertension to such dietary habits. Nor was it possible to involve the intake of protein, which, in general, was lower than that of Western populations and in many cities consisted largely of vegetable proteins. "Westernization," i. e., the adoption of European culture, habits, and food, was little apparent, except among a few of the well-to-do, for income levels are very low in all these countries. The author believes that environmental factors, so far unrevealed, played the leading causative role.

One of the most interesting and unexplained results of this study is the predilection of hypertension to make its consequences obvious either on the vessels of the brain or on the heart in different localities. Thus, cerebral hemorrhage as the fatal outcome has far outdistanced heart failure in Taipeh, Bangkok, and Agra, while cardiac disease is as predominant in Manila, Beirut, Bombay, and Lucknow as it is in the United States. Civilian Chinese in Formosa and Hong Kong are more apt to die of apoplexy than heart failure. Thus, it appears that cerebral hemorrhage is a much more common outcome of hypertension among peoples of the yellow and brown races than among Indo-Europeans or Semites in the cities visited. There was no obvious relationship of the amount or kind of dietary fat or salt to these consequences of hypertension. This study serves to dispel unproved rumors that hypertension does not occur in some Oriental countries.

Cardiovascular Disease in Arachnodactyly. F. S. P. Van Buchem. Acta med. scandinav. **161**:197-205 (No. 3) 1958 (In English) [Stockholm].

The diagnosis of arachnodactyly is important because this condition is not infrequently combined with abnormalities of the eyes and especially of the heart, aorta, and pulmonary artery. The patients are usually tall and of asthenic body build. Because the extremities are very long, they have an arm span that exceeds body height. They have strikingly long and thin fingers and toes, a muscular system that is usually hypotonic and insufficiently developed, a slight layer of subcutaneous fat, and flaccid articular ligaments permitting abnormal joint movements. The patients suffer from kyphosis, kyphoscoliosis, flatfeet, genu valgum, and sometimes a funnel chest or pectus carinatum. The head is dolichocephalic, the face is long and narrow, the palate has a high arch, and the teeth are often irregular. The characteristic longitudinal growth of these patients starts at an early age, and not infrequently in younger patients it is so marked that the final height is abnormal. Moreover, in younger patients the bone age may be 3 or 4 years higher than the chronological age. The cardiovascular abnormalities which the author observed in patients in this category included aneurysms of the ascending aorta, thoracic descending aorta, abdominal aorta, and pulmonary artery, aortic coarctation, pulmonary stenosis, left-sided vena cava superior, ventricular septal defect, and "arachnodactyly heart."

Pulseless Disease. R. di Bello, O. Etorena and R. Rodríguez Barrios. An. Fac. med. Montevideo 43:37-42 (Jan.-April) 1958 (In Spanish) [Montevideo, Uruguay].

A woman with subjective and objective symptoms of circulatory disorder due to occlusion of the main branches arising from the aortic arch was observed at the age of 23 years and again at 37. At the first consultation the patient complained of pain in the arms, of occasional precordial pain which radiated to the back, and of transient hemiparesis. The pulse arising from the aortic arch was absent. Arterial pulsation in the legs was present in all the areas of usual palpation for its detection. The reaction for syphilis was negative. A diagnosis of syndrome of the aortic arch was made. The patient had antisyphilitic treatment for 1½ years, after which she said she felt better and did not report for consultation for 12 years. On the second consultation all the early symptoms presented a slow course, with periods of improvement and relapse. New symptoms consisted of occasional transient loss of memory and loss of vision, irritability, and bilateral facial pain during mastication. The erythrocyte sedimentation rate was increased on both the first and the second examination. On auscultation, there was a thrill over the left supraclavicular fossa after the systole. The patient did not have syphilis or diabetes. Examination of the fundus of the eyes showed the characteristic presence of venous microaneurysms. A diagnosis of pulseless disease from occlusion of the main branches of the aortic arch was made because of the negative results of tests for syphilis, the lack of thrombi, the increased velocity in the sedimentation of the erythrocytes, and the sex and age of the patient. A treatment with corticosteroids was given the patient for more than a year, up to the present time, with marked improvement in the symptoms. The authors direct attention to the value of corticosteroids as symptomatic treatment of pulseless disease.

Spontaneous Pneumothorax in Asian Influenza. R. I. H. Welsh. South African M. J. 33:817-818 (Aug. 16) 1958 [Cape Town].

During the epidemic of Asian influenza, which was at its height in the Transvaal Province of the Union of South Africa during July and August, 1957, about 200 nurses with this form of influenza were admitted to the General Hospital in Pretoria. In 2 of these nurses spontaneous pneumothorax developed, and both of them died. The author believes that in this condition air finds its way into the perivascular tissue planes of the lung via ruptured alveoli, bronchioles, or a bronchus and spreads toward the mediastinum. Its path may then follow the fascial plane of the great vessels into the neck and present clinically as surgical emphysema. A build-up of pressure in the mediastinum may result in a rupture of the pleural covering, with the development of pneumothorax. It is likely that this was the sequence of events in the first patient. Air rarely leaks into the interstitial pulmonary tissues without predisposing causes. In this instance atelectasis of the right lower lobe, with overinflation of adjoining areas, bronchospasm, and cough, was sufficient to predispose the lung to this condition. A pneumatocele bursting into the interstitial lung tissue would have been a ready explanation for the sequence of events.

The spontaneous pneumothorax in the second patient was the result of rupture of a pneumatocele into the left pleural cavity. Pneumatoceles forming in areas of consolidation and resultant spontaneous pneumothorax from their rupture are characteristic roentgenologic findings in staphylococcic pneumonia. Staphylococcic pneumonia seems to occur most commonly as a complication of influenza. In the 1957 epidemic of Asian influenza Staphylococcus pyogenes var. aureus was the most dangerous secondary invader. The sputum culture of coagulase-positive staphylococcic and characteristic roentgenologic signs of pneumatoceles in this patient confirmed the diagnosis of a secondary invasion. That the improvement after release of the tension within the pleural cavity was only temporary indicates the overwhelming nature of the combined infection.

Plasma-Clearing Effect of Gastric Mucin in Healthy and Atherosclerotic Subjects Under Basal Conditions. B. Rossi and V. Rulli. Circulation 18:397-399 (Sept.) 1958 [New York].

The authors determined photometrically the optical density of the plasma obtained from 5 apparently healthy persons and from 10 patients, presumed to have atherosclerosis because of a history of myocardial infarction or of definite anginal symptoms with clear-cut electrocardiographic changes, who had been fasting for at least 12 hours. The determinations were made immediately and again after 20 hours at room temperature. Although the optical density of the plasma varied in the different persons and at different times, it remained unchanged during the 20-hour observation period. The densitometric curve was higher among the atherosclerotic patients than among the healthy persons. The determinations of the optical density of the plasma were repeated a few days later on the same persons who this time were given 250 mg. of gastric mucin before the determinations were made. Administration of gastric mucin was always followed by a reduction in the optical density of the plasma. In both groups the maximal reduction occurred at the end of the third hour. The magnitude of the clearing effect at this time was 30% for the healthy persons and 26% for the patients with atherosclerosis. The clearing effect was similar to that of heparin in regard to constancy and degree, but differed insofar as it lasted longer and did not increase with the passage of time in vitro at room temperature. The mechanism underlying the clearing effect of gastric mucin is not clear, but it seems likely that it is not due to an enzymatic effect of the lipoprotein lipase type, such as the one that is apparently responsible for the heparin clearing effect.

Studies in Cystic Fibrosis of the Pancreas: Occurrence of Rectal Prolapse. L. L. Kulczycki and H. Shwachman. New England J. Med. 259:409-412 (Aug. 28) 1958 [Boston].

This survey comprises 386 patients with cystic fibrosis of the pancreas, 85 (22.6%) of whom gave a history of rectal prolapse. There were no significant differences regarding the sex of the patients. The initial prolapse occurred most commonly between 1 and 2 years of age; in 67 patients (78.6%) the prolapse occurred before a diagnosis of cystic fibrosis of the pancreas was made. Eight patients had prolapse on 1 occasion, and 46 had prolapse on more than 10 occasions. In 46 patients (54.1%) the duration of the complaint was less than 1 year, although in some cases it recurred over a period of more than 5 years. Analysis of the data revealed that many more cases were diagnosed early in life in the larger group in whom rectal prolapse never developed. In most instances rectal prolapse was partial with a descent of the mucosa alone, manual replacement usually being accomplished readily. In 16 patients rectal prolapse was the principal complaint for which parents sought medical advice, and in 2 other patients the attending physician recognized the rectal prolapse as one manifestation of a general nutritional or metabolic problem. In 14 patients the problem was considered a local one until more striking manifestations of cystic fibrosis of the pancreas developed.

In retrospect, a more carefully taken history and physical examination, combined with the performance of a few simple laboratory tests, such as the stool trypsin and chloride imprint tests and roentgenogram of the chest, might have given a clue to the pathological process. Mention is made of the long interval between the initial complaint of rectal prolapse and the diagnosis of cystic fibrosis of the pancreas. In 7 patients the diagnosis of cystic fibrosis was made between 3 and 10 years after the initial episode of rectal prolapse; in 4 cases the interval was 1 to 3 years, and in 5 cases it was less than 6 months. In only 4 patients was the nutritional status of the patient considered good. Only 2 patients had severe pulmonary changes; 1 was free of recognizable pulmonary involvement; and the remaining 13 had varying degrees of pulmonary changes. The institution of dietary therapy, primarily a high-protein and a reduced fat intake, combined with pancreatic replacement therapy, plus antibiotics to control the pulmonary infection, will usually suffice to correct many of the factors responsible for rectal prolapse. The earlier the diagnosis of cystic fibrosis of the pancreas, the less the likelihood of rectal prolapse.

The Blood Volume After Plasma and Blood Transfusions. E. Wollheim and K. W. Schneider. German M. Month. 3:237-240 (Aug.) 1958 (In English) [Stuttgart, Germany].

The authors studied the behavior of the "active" plasma and blood volume in healthy persons and hospitalized patients after 84 plasma transfusions, each of which varied from 450 to 460 cc., and 49 whole blood transfusions, each of which varied from 440 to 450 cc. The term "active blood and plasma volume" refers to the plasma volume, which was determined by differential photometry within 4 to 10 minutes after the injection of 10 cc. of 0.2% Evans blue (T 1824), and to the red blood cell volume calculated from the hematocrit reading. The results of these determinations were compared with those obtained by the analysis of simultaneously drawn samples for red blood cells tagged with radioactive phosphorus (P^{32}) or radioactive chromium (Cr^{51}). The plasma and whole blood determinations were made before the transfusions and at various intervals after the transfusions over a period up to 18 hours.

An increase in plasma volume was observed after 52 (62%) of the 84 plasma infusions and after 23 (47%) of the 49 whole blood transfusions. The plasma volume remained unchanged after 32 (38%) of the plasma transfusions and after 26 (53%) of the whole blood transfusions; in the absence of any increase, the plasma or blood either may have passed into the capillary network with lower circulation or may have entered the extravascular tissues already during the transfusion. An increase in plasma and blood volume occurred particularly in persons in whom plasma or blood volume had been decreased before the transfusion was given. These findings suggest a volume-regulating mechanism. An increase in volume appeared to be more likely after the transfusion of plasma than after that of whole blood.

Tetanus and Chronic Ulcers of the Legs. P. Riis. Nord. med. 60:1048-1049 (July 24) 1958 (In Danish) [Stockholm].

Between 1940 and 1958, 88 patients with non-neonatal tetanus were admitted to the epidemiologic department of the Blegdam Hospital in Copenhagen. In 10 patients, between the ages of 19 and 70 years, the infection was apparently through chronic ulcers of the legs. Nine of these ulcers were varicose, and one was due to erythema induratum. Toxigenic tetanus bacilli were found in excised ulcer tissue from 5 patients. The course of tetanus in the patients in whom the portal of entry was one or more ulcers of the leg was usually protracted, and in 2 it was fatal. In patients with chronic leg ulcers the period during which conditions for growth of Clostridium tetani are present is longer than in patients with smaller traumatic wounds. Chronic varicose ulcers seem to have become relatively more important as portals of entry for Cl. tetani in recent years, as tetanus infections from purely traumatic lesions have been reduced through widespread prophylaxis. Patients with chronic ulcers of the leg should be immunized against tetanus; the vaccination entails no risk.

The Carpal Tunnel Syndrome. J. B. Lyons. Irish J. M. Sc. 6:382-388 (Aug.) 1958 [Dublin].

When fully developed, the carpal tunnel syndrome is characterized by pain and tingling in the hand in the distribution of the median nerve, impaired appreciation of light touch, pin-prick, and tactile discrimination in the fingers over the median territory, weakness of the abductor pollicis brevis and opponens pollicis, and wasting of these muscles causing a distinctive, shelf-like, partial thenar atrophy. Impairment of fine movements, e. g., picking up small objects between thumb and fingers, is invariable. The condition is frequently bilateral. Incidence is highest in the 5th and 6th decades and is commoner in women. The syndrome may occur spontaneously but has been described in a variety of conditions which cause encroachment on the carpal tunnel. The author tabulates the salient points in the clinical pictures of 11 patients with the carpal tunnel syndrome. All the patients were in the 4th decade or older, and all but 3 were women. Pain and/or paresthesia were the main symptoms.

The author discussed the relationship of the carpal tunnel syndrome to acroparesthesia, pointing out that this term has been used to designate a clinical picture most commonly seen in middle-aged women of the working class affected by an unpleasant and distressing tingling involving one or both hands. Acroparesthesia is usually most troublesome at night, preventing sleep or waking the patient and causing her to hang the limb over the side of the bed or to get up and pace the floor seeking relief; in the morning the fingers feel clumsy and swollen. The etiology of this condition has been ascribed variously to cervical osteoarthritis, cervical rib, and the thoracic inlet syndrome. On a suggestion that acroparesthesia is caused by median nerve compression at the wrist, a number of patients have been treated successfully by division of the transverse carpal ligament. In support of the contention that the lesion responsible is situated at the wrist, it was pointed out that frequently the 5th finger is unaffected, that careful sensory testing will reveal loss of median distribution, and that a varying degree of partial atrophy may be present. The essence of a test that is sometimes helpful is that obliteration of the blood supply to the forearm by a sphygmomanometer cuff may cause in some cases of median nerve compression a rapid onset of distressing tingling and pain, most marked in the thumb, index, and possibly ring fingers, or the development of sensory loss in the median territory. Splinting of the wrist may have diagnostic as well as therapeutic value.

Ulcerative Colitis. E. S. R. Hughes. M. J. Australia 2:181-185 (Aug. 9) 1958 [Sydney].

The author has reported on 58 men and 70 women with ulcerative colitis who have been observed in Melbourne since 1950. Most of the 128 patients were between the ages of 20 and 50 years. Ulcerative colitis was mild in 61 patients, of severe chronic type in 55, and of severe acute or fulminating type in 12.

As to the first group, the inflammation was mild in patients with proctitis, and it appeared likewise to be mild in the zone of transition between the normal and the inflamed mucosa in patients with the more severe form of proctocolitis. In 43 of the 61 patients with mild manifestations, the inflammation was limited to the rectum or to the rectum and rectosigmoid section, and in 18 patients the more proximal part of the colon was involved. The external appearance of the intestine was normal, and the lumen was readily distensible. Radiologically, the function appeared normal. Reassurance that cancer was not the cause of symptoms was sufficient treatment for a large number of patients with this type of ulcerative colitis. Increased hours of sleep, a low-residue diet, and the occasional insertion of bland suppositories proved useful in a number of the more resistant patients. Antibiotics did not exert any permanent effect on the disease. Psychotherapy appeared to be a useless method of treatment. No patient in the group with mild manifestations has advanced to a stage where surgery has been considered.

In the 25 men and 30 women of the second group with severe chronic manifestations, nonsurgical treatment of ulcerative colitis did not produce more than temporary relief. Longer hours of rest, a nonresidue diet, and transfusions of whole blood accomplished more than prolonged antibiotic therapy did. Steroid therapy was not used in any extensive trial. It is generally accepted that for patients with this type of the disease surgical treatment is the best method, but 9 of the 55 patients have not yet given their consent for such treatment, and only 2 have made arrangements to undergo surgery later. Four patients in this group died of carcinoma. The remaining 39 patients were subjected to surgical treatment. Pathological examination of the surgical specimens obtained from 35 of these patients who underwent colectomy revealed inflammatory changes. These changes were confined to the descending colon in 4 patients. There was involvement of the whole colon except the cecum and ascending colon in 6 patients, involvement of the whole colon but not the ileum in 7, and involvement of the ileum in 18. Diarrhea had been present for years, associated with anemia, loss of weight, and chronic fatigue. Exacerbations and remissions were characteristic of this group. In 8 of the 128 patients malignant growth was superimposed on the colitis. Seven of these 8 patients with carcinoma of the colon belonged to a group of 19 with a history of colitis for 10 or more years; the 8th patient had had a history of colitis of 7 years' duration. These data show that malignancy may supervene in patients with ulcerative colitis of long duration.

In the third group of 6 men and 6 women with severe acute ulcerative colitis, sigmoidoscopy revealed ulceration of the mucous membrane. The intervening bridges were pale and edematous or red and friable. The chief diagnostic difficulty lay in deciding whether or not peritonitis or peritoneal abscess was present. As a rule, laparotomy was necessary. In each patient turbid fluid was present in the peritoneal cavity, but in only one was there free gas. This latter patient, aged 62 years, had been treated with cortisone without success. Ten of these 12 patients were subjected to surgical treatment, and on each the operation was performed as an emergency procedure. Ileostomy and subtotal colectomy were performed on 5 patients; 1 patient died. On the remaining 5 patients ileostomy and proctocolectomy were performed; again 1 patient died. Two patients did not submit to operation, and both died.

Surgery of ulcerative colitis has improved during the past few years. The colon can be removed in a single stage. Ileostomy and the prevention of complications related to this construction are better understood; the appliances used in ileostomy have been simplified. The mortality associated with ulcerative colitis may be reduced by early operation in acute fulminating cases and by urging more patients partially disabled by chronic ulcerative colitis to undergo surgery.

Cushing's Syndrome in Childhood: Report of Case of Adrenocortical Carcinoma with Excessive Aldosterone Production. W. P. U. Jackson, B. Zilberg, B. Lewis and D. McKenzie. Brit. M. J. 2:130-133 (July 19) 1958 [London].

Adrenocortical overactivity in childhood may produce 2 distinct syndromes. The adrenogenital syndrome caused by excessive production of androgens manifests itself in 3 ways: pseudohermaphroditism and virilism in a female and a "pocket Hercules" variety of isosexual precocity in a male. An excess of glucocorticoids results in Cushing's syndrome without masculinization. The authors report a characteristic "mixed picture" of a Cushing syndrome and an adrenogenital syndrome in a 2½-year-old girl. Since the age of one year there had been a rapid gain in weight, and at this age pubic and axillary hair appeared. Physical examination revealed an obese child with Cushing-like facies and signs of virilism. The patient had a plethoric appearance, a strong body odor, an enlarged clitoris, and a well-marked "buffalo neck," although there was no true breast development. Roentgenograms of the long bones showed normal bone age and the absence of osteoporosis, and pyelograms revealed normal functioning kidneys, with the exception that the left kidney was depressed and a mass was visibly present above it. The 24-hour urinary output of 17-ketosteroids was 39 mg., of 17-ketogenic steroids 11.6 mg., and of aldosterone 75 mcg., the normals of which are less than 2 mg., 3 mg., and 10 mcg. respectively. The patient received 50 mg. of cortisone and was later subjected to a left-sided adrenalectomy. The blood pressure dropped from the initial 140/90 to 100/70 mm. Hg. Five to 12 weeks after the operation the patient had lost a total of 7 lb.; she was no longer plethoric; the facial eruption had diminished; the "buffalo hump" on the neck had disappeared, as had the body odor; and the clitoris was smaller. Hirsuties was still present, although the urinary output of 17-ketosteroids had fallen to 1 mg. per 24 hours. Seven months after the operation the clitoris was of normal size, and the pubic hair had disappeared.

Cone Shell Stings: Recent Cases of Human Injury Due to Venomous Marine Snails of the Genus Conus. A. J. Kohn. Hawaii M. J. 17:528-532 (July-Aug.) 1958 [Honolulu].

The author discusses 8 hitherto unreported cases of injury sustained by man and due to stings of marine mollusks of the genus Conus. Five of these occurred in the Hawaiian Islands, and the persons affected were stung by the mollusks while collecting cone shells. The 6th case occurred in the Marshall Islands, and the 7th in the Mariana Islands. No cases of Conus stings have previously been reported from these 3 archipelagoes. The 8th case occurred at Hope Island, Australia. Five of these 8 cases were caused by 4 species of Conus not previously known to be toxic to man, namely, Conus lividus, C. pulicarius, C. obscurus, and C. nanus. All species of Conus are potentially dangerous to man, but certain species are particularly venomous The latter are often characterized by relatively thin univalve shells with wide apertures, which may flare basally. The size of the cone shells varies from 3 to 23 cm., (1 to 9 in.). It seems probable that the larger the size the larger the quantity of venom delivered. Some large species, however, have a rather poorly developed venom apparatus and are likely to be of little danger to man despite their size. According to Hinegardner of the department of zoology of the University of Hawaii, the venom apparatus of the cone shell consists of the following parts: a muscular bulb, which is attacked to a long, convoluted venom duct, in which the venom is secreted; a radula sheath, in which the radula teeth are produced and stored; a muscular pharynx; and an extensible proboscis. A salivary gland is attached to the radula sheath. Prior to the actual sting, the radula tooth is forcefully inserted, by the proboscis, into the mollusk's victim. Then the venom is injected through the hollow tooth, which is held at its base by the end of the proboscis. How the venom is forced through the tooth is not clear. The living animals should be handled, if necessary, with special care.

Seventeen cases of Conus stings had been reported previously by other workers, and 1 additional case, which occurred in the Seychelles Islands, has come to the attention of the author since he submitted his paper for publication. Thus, a total of 26 cases of Conus stings are now known. Of these, 5 due to C. geographus and C. textile were fatal, but none of them occurred in the Hawaiian Islands. The symptoms resulting from Conus stings vary considerably. Localized ischemia cyanosis, and numbness in the area about the wound or a sharp stinging or burning sensation are usually the initial symptoms. In severe cases paralysis of the voluntary muscles begins early. Knee jerks are generally absent. Aphonia and dysphagia occasionally become very marked. Blurring of vision and diplopia are commonly present. Nausea may be present. Coma, cardiac failure, and respiratory distress have been reported by other workers. Immediate lancing of the wound and sucking of the venom from it are recommended. Further treatment is symptomatic.

Chest Pain of Colon Origin. E. D. Palmer. Gastroenterologia 90:15-21 (No. 1) 1958 (In English) [Basel, Switzerland].

The author, who is connected with an American hospital in Germany, observed in the course of a year 30 patients with the primary complaint of chest pain and with a colon gas syndrome as the explanation. The gaseous distention involved the hepatic or splenic flexures of the colon, usually the latter. Almost always colon symptoms per se were wholly absent, as were other abdominal symptoms, and the colonic basis for the problem was not apparent to the patient or often at first to the physician. In 26 of the 30 patients the gas syndrome was the whole problem, and in the remaining 4 the gas syndrome prolonged and superimposed atypicalness on the chest pain of acute myocardial infarction (Laubry-Soule syndrome). The 4 patients with Laubry-Soule syndrome were patients who, within

3 or 4 days of acute myocardial infarction, experienced new pain and a distressing feeling of fulness in the anterior part of the chest on the left, had difficulty in taking a deep breath without true dyspnea, and had a tremendous collection of gas in the splenic flexure with elevation of the left leaf of the diaphragm, all in the absence of any sign of extension of infarction or of cardiac decompensation. These patients had no difficulty in distinguishing this new pain from that of the infarction.

The 30 patients included 16 women and 14 men, ranging in age from 22 to 54 years. The duration of painful symptoms prior to study varied from less than a day to several years. Three patients presented themselves as emergency problems of acute new chest pain, but most had had recurrent pain for a few weeks to several months, with varying intensity from time to time. All the patients complained of pain which was predominantly paroxysmal, the paroxysms being sudden in onset, lasting from a minute to a couple of hours, and subsiding rather rapidly, either completely or leaving persistent heavy discomfort in their wake. In the outpatient clinic of the American-German hospital, chest pain of colon origin was about 3 times as common as duodenal ulcer. This symptom complex seems to be more of a problem in this overseas region than back home. In a fair portion of patients the onset of symptoms coincided with their overseas movement. Patients often suggested that change in food and water might be responsible. Treatment with buttermilk was remarkably effective in some cases, rather ineffective in others.

Phaeochromocytoma, Diabetes and Glycosuria. P. Freedman, R. Moulton, M. L. Rosenheim and others. Quart. J. Med. 27:307-321 (July) 1958 [London].

The authors report on a 37-year-old man and on 3 women, between the ages of 32 and 65 years, with pheochromocytoma which caused severe diabetes mellitus in 2 of these 4 patients and persistent glycosuria in the other 2. A diagnosis of diabetes mellitus had been made in 3 of these patients before the adrenal tumor was discovered, and many of their symptoms had been considered by other physicians, who did not have experience with pheochromocytoma, to be manifestations of anxiety. Severe hypertension is rare in idiopathic diabetes mellitus but is common in diabetes associated with pheochromocytoma. Advanced hypertensive retinopathy, as distinct from diabetic retinopathy, does not often occur in idiopathic diabetes mellitus but is common in patients with pheochromocytoma. In any diabetic patient with severe hypertensive retinopathy as distinct from diabetic retinopathy, the pressor amine content of the urine should be measured. The hypertension in diabetes caused by pheochromocytoma may be paroxysmal or sustained, and the blood pressure is frequently raised between attacks, as was observed in 2 of the 4 patients. Similarly, the disturbance in carbohydrate metabolism may be accentuated in paroxysms, but usually, if it is severe enough for the patient to have diabetic symptoms, glycosuria and high blood sugar levels are constantly present, as they were in these 2 patients. A high blood sugar level during attacks, sometimes followed by glycosuria, is common in patients with pheochromocytoma, and such patients may have a diminished glucose tolerance—though they have not been considered as diabetics, as was the case in the 4th patient. Surgical removal of the tumor led to considerable improvement of diabetic symptoms in all 4 patients, but the glucose tolerance test still showed considerable intolerance of carbohydrates in 2 patients, while it reverted rapidly to normal in 1. A systematic search for similar cases (including determination of the excretion of pressor amines in the urine) was made by the authors among 1,100 patients with diabetes mellitus attending the diabetic clinic of the University College Hospital in London, and 2 additional possible cases were found.

The mechanism by which pheochromocytoma may cause diabetes is uncertain. It is considered that the high plasma concentration of epinephrine, and to a much smaller extent of arterenol, causes a rise in blood sugar by accelerating glycogenolysis in the liver. This may well increase the rate of secretion of insulin by the pancreas and occasionally produce a temporary or permanent exhaustion of the islets of Langerhans. It is also possible that epinephrine may antagonize insulin by its action on the anterior pituitary gland, causing an increased secretion of corticotropin and thus indirectly stimulating the secretion of hydrocortisone. Insulin sensitivity tests carried out in one patient with diabetes caused by pheochromocytoma showed insulin resistance, thus affording indirect evidence of an increase in insulin antagonists. The insulin requirements are usually greatly decreased within 24 hours after removal of the tumor, and the patients may be completely cured of their diabetes. Pheochromocytoma should be suspected in any diabetic patient with severe hypertension and in any hypertensive diabetic patient with unusual symptoms.

Treatment of Strongyloidiasis: New Drugs. J. Asfora and M. A. Maranhão. Rev. brasil. med. 15:325-330 (May) 1958 (In Portuguese) [Rio de Janeiro].

The incidence of strongyloidiasis varies between 9 and 17% among the population of Brazil. The classical treatment, which consists in the intraduodenal instillation of 40 cc. of a 1% methylrosaniline chloride (gentian violet) solution, gives a recovery rate of less than 10% of the cases. Brazilian researchers recently reported good results from the intraduodenal instillation of methylrosaniline solution by the following technique: 1. An Einhorn sound is passed through the nose into the duodenum and left in place for 20 minutes. 2. A solution containing 60 Gm. of Panemax (a papain preparation) in 250 cc. of distilled water is then instilled, followed by the instillation of a vial of hyaluronidase. 3. Two or 3 minutes later 40 cc. of a 1% methylrosaniline solution is instilled. 4. The intraduodenal sound is removed 3 minutes later. Papain acts as a mucolytic substance by exposing the duodenal mucosa to the action of the methylrosaniline solution, whereas hyaluronidase favors diffusion of the solution over the mucosa.

Twenty patients with strongyloidiasis were treated by this technique at the clinic of the faculty of medicine of the University of Recife. The patients were between the ages of 20 and 40 years. Sixteen patients tolerated the treatment well, but 4 vomited. The treatment was repeated in 2 of the 4 patients who vomited. As a result of the treatment the clinical symptoms of duodenal parasitism disappeared, and examination of feces at late intervals proved the absence of nematodes of the strongyloides genus. The patients in whom good results were obtained included 3 with strongyloidiasis alone, 3 with strongyloidiasis and ascariasis, and 6 with strongyloidiasis and infection with other intestinal parasites. The authors conclude that the combination of papain, hyaluronidase, and methylrosaniline gives better results than any other treatment for the cure of duodenal strongyloidiasis and ascariasis (80%). When the treatment is repeated after a failure, the good results are 100%. Intolerance showed only in vomiting of the drugs; pain or any other unpleasant symptoms did not occur. The treatment is practical, economical, and well tolerated.

Systemic Lupus Erythematosus Simulating Acute Surgical Condition of the Abdomen. V. E. Pollak, W. J. Grove, R. M. Kark and others. New England J. Med. 259:258-266 (Aug. 7) 1958 [Boston].

The authors present observations on 14 patients in whom abdominal symptoms developed that were severe enough to suggest a surgical emergency. In all 14 patients the diagnosis of systemic lupus erythematosus was made on the basis of clinical observation and laboratory data. In all but 4 patients the diagnosis was confirmed by histological study of kidney specimens obtained either by biopsy or at autopsy. The clinical picture varied considerably from patient to patient. In 10 patients the abdominal illness was the result of vascular lesions ("lupus vasculitis") in the submucosa and subserosa of the intestine and its appendages and of vascular lesions in the retroperitoneal, peripancreatic, and periadrenal connective tissues. In some these lesions were widespread; in others they were localized. It was not surprising, therefore, to find that many different clinical diagnoses were made in these patients, such as acute appendicitis, acute cholecystitis, perforating peptic ulcer, volvulus, paralytic ileus, obstruction of the small intestine, severe gastroenteritis, parametritis, infection of the broad ligament, and infective peritonitis. All 10 patients complained of abdominal pain, which in 5 was dull and persistent and either involved the entire abdomen or was limited to the lower abdomen. The most frequent roentgenologic finding was distention of the large or the small intestine or both. A single attack of acute abdominal symptoms occurred in 5 paitents, and 2 or more attacks occurred in the other 5. The problems presented by these patients and the disease causing their illness are illustrated in case histories.

A clinical diagnosis of pancreatitis was made in 4 of the 14 patients. In the 3 who died, lesions were found post mortem in the pancreas and elsewhere in the abdomen. In one of these patients acute pancreatitis developed when the patient already was severely ill with renal failure due to lupus glomerulonephritis. The serum amylase level was elevated, suggesting that there was true necrosis of the pancreatic acini. This was confirmed at autopsy. The lesions in the pancreas did not appear to result from systemic lupus erythematosus. The large arteries of the pancreas were the seat of polyarteritis nodosa in one case. In the other, the small arteries and arterioles were occluded by platelet thrombi—typical of thrombotic thrombocytopenic purpura. In neither was there necrosis of the pancreatic acini, nor were the serum amylase levels elevated. Both patients had definite clinical and pathological evidence of systemic lupus erythematosus. The details of the clinical illness and pathological findings in one of these patients are presented.

The differential diagnosis of acute surgical condition of the abdomen due to systemic lupus erythematosus could be made with some confidence when the patient had concurrent involvement of other organs by the lupus and particularly when there was an abnormal urinary sediment and leukopenia. Even when a diagnosis of acute abdominal emergency from this cause has been made, it must be remembered that in such cases intercurrent, unrelated acute abdominal emergencies may develop. Exploratory surgery should not be undertaken lightly, for the trauma of the operation may result in a further deterioration of the patient's already serious clinical state. When this diagnosis is made, the patient should be treated vigorously with adrenal corticosteroids, and the drug should be given by the intravenous route if necessary. The authors found that the acute abdominal symptoms improved within 24 or 48 hours of the start of treatment with large doses of adrenal corticosteroids.

SURGERY

Persistent Post-traumatic Fluid Fistulas: Anatomoclinical and Therapeutic Study of 20 Cases. J. Calvet, G. Lazorthes, A. Ribet and Y. Lacomme. Presse méd. 66:1305-1307 (Aug. 2) 1958 (In French) [Paris].

Fractures of the base of the skull are often complicated by a transient escape of cerebrospinal fluid through a natural opening in the face. Persistence of such a flow for more than a week, however, is rare and indicates the existence of an osteomeningeal fistula. Conservative treatment, which consists in keeping the patient as quiet as possible in a recumbent or semirecumbent position, in reducing the fluid intake, and in giving antibiotics (especially penicillin), both systemically and in aerosol form, sometimes results in a definitive cure of the fistula but does not always eliminate the danger of meningitis or cerebral abscess.

Spontaneous cures usually take place within the first 10 days after the injury but may occur later, especially when the fluid escapes through the ear. Conservative treatment, however, should not be continued for more than about 3 weeks because of the serious nature of the infectious complications to which patients with osteomeningeal fistulas are always subject. Meningitis may appear long after an apparent cure of the fistula (22 months in one of the authors' 20 patients) and is no less severe then than when it develops promptly. Immediate surgical treatment is indicated only in patients with an open fracture of the frontal sinus, but conservative treatment may have to be abandoned in favor of early operation if meningitis develops or if the flow is so abundant that there is a danger of cerebral collapse.

A unilateral frontal flap usually provides adequate access to the lesion. Closure of the osteomeningeal opening can be secured in most cases by packing with fragments of muscle: one is applied to the internal aspect of the dura mater, and another, coated with sulfonamide powder and penicillin, is used to fill the opening in the bone. This method of closure, which has been used exclusively during the last 5 years, has apparently produced better results than those obtained earlier when other methods and materials were tried.

Surgery for Congenital Coronary Artery Arteriovenous Fistulae. E. H. Fell, M. Weinberg Jr., A. S. Gordon and others. A. M. A. Arch. Surg. 77:331-335 (Sept.) 1958 [Chicago].

The authors report on an 18-year-old girl and 3 boys, aged 14 months, 3 years, and 9½ years, respectively, who were operated on for anomalous coronary arteries entering directly into the venous system. In the girl, a large anomalous branch of the left coronary artery communicated with the outflow tract of the right ventricle, but the condition was not associated with an aneurysm of the artery or ventricle. In the 2 older boys the right coronary artery with a diffuse aneurysm communicated directly with the right ventricle. In the 14-month-old boy the large right coronary artery emptied into an aneurysm at the apex of the right ventricle. The anomalies in these 4 patients were believed to be congenital. The histories of the 3 boys revealed cardiac murmurs heard as early as the ages of 1, 1½, and 7 months respectively. Development was normal in each patient. All the children showed cardiac enlargement, and a machinery murmur was heard at the apex or to the right of the sternum in each patient. The catheterization studies revealed a left-to-right shunt into the right ventricle. Angiocardiograms and aortograms localized the lesions and were diagnostic in the youngest and in the oldest boy in whom the condition was correctly diagnosed before the surgical intervention; in the 3-year-old boy the preoperative diagnosis was one of rupture of the sinus of Valsalva into the right ventricle. In the girl, who did not have angiocardiographic studies, the condition was believed to be a patent ductus arteriosus before the surgical intervention.

Surgical correction of the anomalies was successful in all 4 patients; the fistulas were closed and the aneurysms resected. Normal cardiac function resulted in all the patients, and no left-to-right shunt exists. These findings suggest that patients with a coronary artery arteriovenous fistula tolerate well closure of the fistula and excision of the aneurysms of the artery or ventricle or both.

A Study of the Treatment of 637 Patients with Trigeminal Neuralgia. D. Ruge, R. Brochner and L. Davis. J. Neurosurg. 15:528-536 (Sept.) 1958 [Springfield, Ill.].

The authors report on 373 female and 264 male patients, between the ages of 15 and 89 years, with trigeminal neuralgia. Fifteen patients had the onset of pain before they reached their 25th year, and 7 noted their symptoms after they were 80 years old. The right side of the face was the site of pain in 393 patients, the left side in 228, and 16 had bilateral pain. Spontaneous remissions of pain for periods of 18 months to 7 years were observed. Extradural preganglionic neurotomy by way of the middle fossa, according to Frazier's technique modified by Adson, was performed on 627 of the 637 patients. Complete sensory section was carried out in 556 patients. Partial selective root section spared the sensory innervation of the eye in 65. The motor root was preserved in 206 patients. There were 4 operative deaths, caused, respectively, by meningitis, subdural hematoma, hemorrhage, and pulmonary infarct.

Transient ipsilateral facial paresis constituted an early postoperative complication in 41 patients, requiring commonly 1 to 4 weeks for recovery. Contralateral facial paresis with prompt recovery was observed in 1 patient, transient lateral rectus muscle palsy was experienced by 5 patients, and transient parotitis occurred in 1 patient. Continuous postoperative follow-up was possible in 513 patients, 303 of whom did not have latent postoperative complications or unfavorable results. Conjunctival infection occurred in 39 patients and corneal ulceration in 19; enucleation of the injured eye was required in 6 of the latter. Postoperative paresthesias were observed in 104 patients, and miscellaneous disturbances in 40. Two patients committed suicide, each of them 8 years after the surgical intervention.

Extradural preganglionic neurotomy is the most effective surgical procedure for the treatment of *trigeminal neuralgia. Properly performed, the operation is an anatomic one which gives relief from* excruciating pain. Most patients, if properly prepared psychologically before the operation for the loss of sensation, which must be incurred for the permanent relief of pain, do not suffer from paresthesias which interfere with their lives. Corneal ulceration occurs only after direct trauma to an insensitive cornea and is not the result of a trophic loss, independent of injury. Facial weakness and herpes of the lips, which may occur immediately after the operation, are caused by excessive and unnecessary handling of the ganglion in the latter instance and by elevation of the dura mater from the floor of the middle fossa too far posteriorly in the first instance. Patients are usually confined to the hospital for 7 to 10 days.

Experiences in the Surgical Treatment of Aortic Isthmus Stenoses (Report on 120 Operated Cases). K. Kremer, H. Hilke and K. H. Willmann. Arch. klin. Chir. 288:513-525 (No. 6) 1958 (In German) [Berlin].

In an earlier report the authors discussed the clinical aspects and the surgical treatment of stenosis of the aortic isthmus, but since then the number of patients with this defect whom they subjected to surgical treatment increased to 120. On the basis of their observations they feel that the customary *classification of aortic isthmus stenosis in infantile* and adult forms merely on the basis of anatomic factors is not satisfactory, because the functional effects of the ductus arteriosus Botalli (direction of the shunt) is of decisive importance. The situational relationship of the stenosis to the ostium of the ductus arteriosus and the absence or presence of a collateral circulation have generally been regarded as the classical differentiating characteristics between the 2 forms. Thus, it is assumed that in the infantile form the lower part of the body is supplied with blood by way of the ductus arteriosus, which is excessively dilated and terminates poststenotically, whereas in the adult form the collateral circulation is well developed because of the prestenotic ostium of the ductus.

The authors observed types of aortic isthmus stenosis that were intermediate between these forms. An adult form and infantile forms, with and without collateral circulation, are presented. A 6-year-old girl was observed, who had isthmus stenosis and a maximally dilated ductus arteriosus with poststenotic ostium; there was no collateral circulation, but despite this there existed a left-to-right shunt with extreme pressure increase in the lesser circulation. The division of the ductus reduced the pulmonary hyptertension immediately, and correction of the moderate isthmus stenosis normalized the pressure in the systemic circulation.

The authors emphasize that patients with stenosis of the aortic isthmus require surgical treatment. *The only contraindications are severe impairment* of the cardiac function, subacute endocarditis or aortitis, and age over 45 years. The prognosis is unfavorable when other congenital defects are combined with the stenosis of the aortic isthmus. The aim of the operation is always the direct anastomosis according to the technique of Gross-Crafoord; however, it should not be forced at the risk of an insecure suture. Transplantations should be restricted to a minimum.

Preparatory Treatment and Operation in Bilateral Bronchiectasis. F. Spath. Arch. klin. Chir. 288:505-512 (No. 6) 1958 (In German) [Berlin].

Resection in patients with bronchiectasis has proved to be one of the most gratifying operations of the thoracic surgeon. This applies particularly to patients with unilateral bronchiectasis. Bilateral involvement has been reported in from 20 to 40% of patients, and while bilateral resections have been successfully carried out, frequently the resection of the main focus will have such a favorable effect on the less seriously involved side that a *second operation will not be necessary*. The author observed 12 patients in whom this was the case and presents the history of one of these. If the lesions are severe on both sides, bilateral resection will be necessary, but the operation should be done first on the more severely involved side.

The results of bilateral resection are favorable, provided that certain essential steps are followed in orderly sequence: (1) exact localization of the bronchiectatic lesions by a special bronchographic technique; (2) careful testing of the respiratory and circulatory function by spirometry, bronchospirometry, oximetry, and spiro-ergometry; (3) effective and prolonged local and systemic preparatory treatment, consisting in sanitization of chronic foci of suppuration, normalization of the blood and of the fluid, electrolyte, and protein economies, also psychotherapy and the administration of vitamins; (4)

proper evaluation of the indications for the operation, and meticulous surgical technique; and (5) systematic and effective after-treatment.

In the preparatory treatment, serial endoscopic suctioning off, irrigation, and instillation of pretested sulfonamides and of antibiotics proved valuable. In a 19-year-old girl with a particularly severe form of bilateral bronchiectasis, additional climatotherapy (sojourn at an elevation of 1,200 meters [3,900 ft.]) proved helpful. A double suction drainage forces the expansion of the residual lung. The application of a depot (long-acting) anesthetic to the irritated intercostal nerves near the surgical wound will facilitate painless expectoration immediately after the patient awakens. All measures that promote expectoration should be employed. Continuous observation of the patient will make possible early recognition of dangerous atelectasis in the residual lung. If atelectasis has developed, endoscopic suctioning off of the bronchial tree should be instituted at once in order to reinflate the remaining lung, because, should atelectasis persist, new ectatic processes will develop.

Tuberculosis of the Breast: Report of 25 Cases. T. T. Yeh. Chinese M. J. 77:63-69 (July) 1958 (In English) [Peking].

The author reports on 1 man and 24 women, between the ages of 17 and 45 years, with tuberculosis of the breast. The right breast was involved in 15 of the 25 patients, and the left in 11; 1 patient had bilateral involvement in successive stages. The outer-upper quadrant was the most common site of the lesion. The interval between noticing a painless lump and obvious local infiltration was usually 1 to 2 months. This fact is of practical significance in early recognition. The duration of the disease in most of the patients varied from several months to 2 years. In cases of long duration, the lesion being deep and its development insidious, the patient was not aware of it, but even in these patients a detailed history might have facilitated differential diagnosis from cancer and nonspecific mastitis. In the early stages the margin of the tubercular lesion was indistinct on palpation, and the breast was usually not enlarged. After a quiescent period the lesion gradually enlarged, and hard and soft areas occurred with irregular margins. At this time the tissues and skin surrounding the mass were infiltrated and adherent. There was mild tenderness, swelling, and reddish discoloration of the skin. Deviation of the axis of the nipple was observed in 9 patients in whom the mass was close to the areola. A huge cold abscess, with pus discharging from the nipple, was observed in 3 patients in whom the mass softened and manifested a cystic sensation. As a rule, constitutional symptoms were absent. The general condition was either good or average in 21 patients.

Tuberculosis of the breast is usually not accompanied by active tubercular lesions elsewhere in the body. The principal routes of infection are probably through the blood stream and the lymphatic system. Pregnancy, lactation, secondary infection, and trauma are important stimulating factors. Tuberculosis of the breast is a localized process, and early diagnosis and treatment can bring about complete cure. The early stage of lesions of the nodular type may be treated conservatively by employing supportive measures and by administration of antituberculous drugs before and after operation. In the series presented early excision prevented spread of the disease and resulted in satisfactory healing of the lesions in 9 patients. When the tuberculous process involves more than one-third of the breast in patients with confluent and scirrhous-type lesions, simple mastectomy combined with preoperative and postoperative administration of antituberculous drugs is the treatment of choice. Antituberculous drugs and other antibiotics may be used simultaneously for the treatment of secondary pyogenic infections. For the treatment of tuberculosis of the breast complicated by external fistulas, early simple mastectomy is advocated. According to the author 7 patients subjected to this treatment obtained satisfactory results.

Idiopathic Retroperitoneal Fibrosis: A Condition Involving the Ureters, the Aorta, and the Inferior Vena Cava. E. Hackett. Brit. J. Surg. 46:3-9 (July) 1958 [Bristol, England].

The disorder becoming known as "idiopathic retroperitoneal fibrosis" consists of a dense flattened plaque of fibrous tissue which lies immediately anterior to the bodies of the lumbar vertebrae and the fascia covering the front of the iliopsoas muscles. It can extend across the midline, surrounding the great vessels, or may be on one side only. It may be confined to the level of the kidneys, to the brim of the pelvis, or to an intermediate area. In the 14 men and 6 women, between the ages of 23 and past 60, whose cases were collected from the literature, the plaque of fibrous tissue always enveloped and progressively constricted some or all of the structures which lie in the same site—the ureters, the aorta, the inferior vena cava, and the common iliac vessels. The histological reports showed the plaque to be composed of normal fibroblasts and collagen with some foci of cells of chronic inflammatory type; it had the general nature of a scar or keloid and not that of a fibroma or fibrosarcoma.

The author reports 2 additional cases of this disorder in 2 men, aged 40 and 54 years. The younger of the 2 died, and autopsy revealed the lesion to be fully developed. In the second patient, laparotomy revealed the lesion to be in an early or abortive stage. These 2 cases bring the total of those reported to 22. Surgical treatment was carried out in all except 1 patient. Of the 21 patients operated on, successful dissection to free the ureters or kidney was carried out in 12, 3 were subjected to nephrostomy only, 2 had nephrectomies, and 4 had diagnostic laparotomies. Irradiation treatment was given to 3 patients; the doses were 600, 840, and 4842 to 6000 r. There was apparent improvement in 2 patients, but no improvement or histological change occurred in 1. So far no satisfactory cause has been proposed for the condition. The author believes that in some, and perhaps in most cases, it is produced by organization of a hematoma or of a fibrinous effusion. The treatment should be surgical.

Acute Pancreatitis and Hyperdiastasuria after Partial Gastrectomy. S. Wallensten. Acta chir. scandinav. 115:182-188 (No. 3) 1958 (In English) [Stockholm].

The author reports an analysis of the incidence of fatal acute pancreatitis and the occurrence of hyperdiastasuria after gastric resection (Billroth types I and II) in patients with peptic ulcer. In a series of 1,769 Billroth II resections there were 12 deaths caused by acute postoperative pancreatitis, while in a comparative series of 605 Billroth I resections there were no deaths attributed to acute postoperative pancreatitis. Hyperdiastasuria occurred in 18 patients (16%) after 117 Billroth II resections and in 5 patients (9%) after 55 Billroth I resections. The difference in the incidence of hyperdiastasuria after the Billroth I and II resections is not considered significant. Whether there is penetration of the ulcer into the pancreas does not seem to affect the incidence of postoperative pancreatic disturbances. Thus, operative treatment may be extended and need not be limited to palliative resection. Although the etiology of postoperative pancreatic disturbance (acute pancreatitis and hyperdiastasuria, respectively) is still relatively obscure, analysis of the data would seem to indicate that their cause is related in some way to the operative method. Duodenal and afferent loop stagnation are adjudged as being of importance in the etiology of postoperative disturbances after Billroth II gastric resections.

Studies During the Immediate Postoperative Period Following Total Body Perfusion. E. C. Matthews, L. C. Clark, F. K. Edwards and others. A. M. A. Arch. Surg. 77:313-318 (Sept.) 1958 [Chicago].

The authors carried out physiological studies during perfusion and the immediate postoperative period in 10 consecutive patients, between the ages of 1 and 15 years, who were operated on for various congenital cardiac defects. Results showed that, if patients are perfused with fully oxygenated blood of normal pH at a rate which yields venous oxygen saturation in excess of 50%, metabolic acidosis does not occur. There is no need to perfuse at alkaline pH's in anticipation of ensuing metabolic acidosis or to administer alkali during the postoperative period. In the postoperative period, a more or less constant pattern for all the patients appeared from the intermittent arterial sampling. Initial pH values were usually low, the lowest being 7.25, but they showed a steady rise, so that most were normal by 3 hours and all were within the range of normal by 6 hours. The carbon dioxide contents initially were elevated and remained so during the sampling period. The carbon dioxide pressure likewise was initially elevated but showed a tendency to fall during the sampling period. The over-all picture was one of mild respiratory acidosis.

Thus, postoperative respiratory acidosis, comparable to that reported in patients undergoing thoracotomy for procedures not involving perfusion, may occur, but it is mild and of short duration. Sudden postoperative deaths, ascribed by other workers to oxygen toxicity, did not occur in these patients, and evidence of oxygen toxicity was not observed in these or other patients who were consistently perfused at arterial oxygen tensions ranging between 500 and 550 mm. Hg. The potential hazard of producing oxygen bubbles in the patient's arterial system exists, since the solubility of oxygen in blood is decreased with increasing temperatures; it is, however, obviated if the blood in the pump-oxygenator is maintained at the temperature of the patient's blood.

Acute Necrotizing (Pseudomembranous) Enterocolitis. A. W. Kay, R. L. Richards and A. J. Watson. Brit. J. Surg. 46:45-57 (July) 1958 [Bristol, England].

The authors report on 1 woman and 15 men, between the ages of 27 and 67 years, with acute necrotizing (pseudomembranous) enterocolitis. Of the 16 patients, 14 had been subjected previously to abdominal operations, and the enterocolitis occurred in them as a postoperative complication. The operation which most frequently preceded the condition was gastrectomy. The enterocolitis was associated with heart disease in the remaining 2 patients. The outstanding clinical feature of the 16 patients was the rapid development of a state of irreversible acute peripheral circulatory failure. Diarrhea was an inconstant feature, but it was sometimes severe. Symptoms occurred within 2 to 6 days after the surgical intervention, and all the patients died within 48 hours of the onset.

Autopsy which was performed on all 16 patients revealed that necrosis of the intestinal mucosa, associated with thrombotic occlusion of the related capillaries and venules, was the most prominent pathological feature. The changes may be widespread, localized, or focal in distribution, and they may occur in any part of the small or the large intestine and occasionally in the stomach. Superficial inflammatory exudation was not a constant finding, although in many patients it did constitute a distinct pseudomembrane. Concerning the causation and pathogenesis of the disease, the authors were unable to confirm the concept that a vasomotor disturbance associated with shock may be a causal condition. Before ascribing a causative significance to antibiotics, it should be noted that necrotizing enterocolitis was recognized, particularly as a postoperative complication, for many decades before their introduction. The hypothesis that necrotizing enterocolitis is directly due to infection of the intestine by enterotoxin-producing strains of Staphylococcus pyogenes var. aureus must be regarded as unproved, and there is considerable circumstantial evidence against the acceptance of this concept. Staphylococcic enteritis and acute necrotizing enterocolitis are probably not directly related, although they may occur together. Attention should be paid to the possibility that other bacteria, such as varieties of Clostridium welchii, might be the cause of acute necrotizing enterocolitis; the possibility that the disease may be due to a virus infection should also be considered. In the postoperative cases the clinical diagnosis between acute necrotizing enterocolitis and high obstruction of the small intestine is difficult; immediate laparotomy is, therefore, advised. Treatment for shock and the administration of erythromycin and adrenal hormones have so far proved ineffective.

Internal-Mammary-Artery Ligation for Angina Pectoris: Its Failure to Produce Relief. R. G. Fish, T. F. Crymes and M. G. Lovell. New England J. Med. 259:418-420 (Aug. 28) 1958 [Boston].

The authors report on the results of bilateral internal mammary artery ligation in a group of 24 selected patients with moderate or severe angina pectoris. All the patients were males, ranging in age from 32 to 64 years. In 22 patients the diagnosis of angina pectoris was made on the basis of a classic history, with transient electrocardiographic ST-segment or T-wave changes accompanying pain, or electrocardiographically proved transmural myocardial infarction at some time in the past. The character, duration, and progression of pain, requirements of glyceryl trinitrate (nitroglycerin), exercise tolerance, and occupational history were carefully noted. Eleven patients (46%) had previous transmural myocardial infarction; 10 (42%) had angina decubitus on admission. In 20 of the 24 patients on whom internal mammary artery ligation was performed, there was an initial marked improvement in the immediate postoperative period, which lasted for approximately 10 to 60 days. This period of improvement was marked by electrocardiographic stability, an increased exercise tolerance, and a reduction in the quantity of glyceryl trinitrate required. This improvement was particularly dramatic in patients who entered the hospital with angina decubitus and who continued to have occasional episodes of rest angina up to the time of operation—an improvement which in the light of subsequent findings is difficult to explain. Two patients died during the subsequent follow-up period, one patient succumbing 3 months after operation of bronchopneumonia complicating influenza, the other death occurring 5 months after operation as a direct result of coronary artery disease. In most of the remaining patients there was definite regression, with development of recurrent angina. The condition was such that at the time of writing there were only 4 patients who in their own opinion experienced moderate improvement and 2 who believed that they were slightly improved. In the remaining 18 patients the anginal syndrome resumed its preoperative course. Whether or not the survival time of these patients has been increased by an operation that failed to alter symptoms is an interesting speculative aspect of this and other surgical attempts to revascularize the myocardium.

Citrate Intoxication: A Clinical and Experimental Study. J. Ludbrook and V. Wynn. Brit. M. J. 2:523-528 (Aug. 30) 1958 [London].

The authors report on 3 men, between the ages of 24 and 55 years, and on a 44-year-old woman who were operated on with the aid of hypothermia for the following conditions: an aortic thrombosis extending up to the level of the renal arteries (2), an aortic aneurysm situated in the region of the 11th to 12th thoracic vertebrae, and a hemangioma of the liver with associated cirrhosis. In the course of the operation the 4 patients were given infusions of citrated blood, and high plasma citrate levels occurred during the infusions. One patient died with signs attributable to citrate intoxication. These observations induced the authors to study the metabolism of the infused citrate in dogs and in normal persons. A linear relationship between the rate of infusion of citrate and the rise in plasma citrate level was observed in normal men and dogs. For each 1 mg. of citrate infused per kilogram of body weight per minute, the rise in plasma citrate level was about 20 mg. per 100 cc. in dogs and 12.5 mg. per 100 cc. in man. By using a constant infusion technique, it was shown that in dogs about 40% and in man about 20% of the infused citrate was excreted in the urine, and the remainder was metabolically destroyed. In both dog and man lowering the body temperature to 28 or 29 C (82.4 or 84.2 F) by surface cooling (hypothermia) was shown to reduce the rate of metabolic destruction of citrate by 30 to 40%.

From these findings it would seem that the infusion of citrated blood at less than 1 pt. (540 cc.) in 5 minutes in an adult is unlikely to cause a dangerous rise in the plasma citrate level, provided reported to 22. Surgical treatment was carried out in all except 1 patient. Of the 21 patients operated on, successful dissection to free the ureters or kidney was carried out in 12, 3 were subjected to nephrostomy only, 2 had nephrectomies, and 4 had diagnostic laparotomies. Irradiation treatment was given to 3 patients; the doses were 600, 840, and 4842 to 6000 r. There was apparent improvement in 2 patients, but no improvement or histological change occurred in 1. So far no satisfactory cause has been proposed for the condition. The author believes that in some, and perhaps in most cases, it is produced by organization of a hematoma or of a fibrinous effusion. The treatment should be surgical.

Acute Pancreatitis and Hyperdiastasuria after Partial Gastrectomy. S. Wallensten. Acta chir. scandinav. 115:182-188 (No. 3) 1958 (In English) [Stockholm].

The author reports an analysis of the incidence of fatal acute pancreatitis and the occurrence of hyperdiastasuria after gastric resection (Billroth types I and II) in patients with peptic ulcer. In a series of 1,769 Billroth II resections there were 12 deaths caused by acute postoperative pancreatitis, while in a comparative series of 605 Billroth I resections there were no deaths attributed to acute postoperative pancreatitis. Hyperdiastasuria occurred in 18 patients (16%) after 117 Billroth II resections and in 5 patients (9%) after 55 Billroth I resections. The difference in the incidence of hyperdiastasuria after the Billroth I and II resections is not considered significant. Whether there is penetration of the ulcer into the pancreas does not seem to affect the incidence of postoperative pancreatic disturbances. Thus, operative treatment may be extended and need not be limited to palliative resection. Although the etiology of postoperative pancreatic disturbance (acute pancreatitis and hyperdiastasuria, respectively) is still relatively obscure, analysis of the data would seem to indicate that their cause is related in some way to the operative method. Duodenal and afferent loop stagnation are adjudged as being of importance in the etiology of postoperative disturbances after Billroth II gastric resections.

Studies During the Immediate Postoperative Period Following Total Body Perfusion. E. C. Matthews, L. C. Clark, F. K. Edwards and others. A. M. A. Arch. Surg. 77:313-318 (Sept.) 1958 [Chicago].

The authors carried out physiological studies during perfusion and the immediate postoperative period in 10 consecutive patients, between the ages of 1 and 15 years, who were operated on for various congenital cardiac defects. Results showed that, if patients are perfused with fully oxygenated blood of normal pH at a rate which yields venous oxygen saturation in excess of 50%, metabolic acidosis does not occur. There is no need to perfuse at alkaline pH's in anticipation of ensuing metabolic acidosis or to administer alkali during the postoperative period. In the postoperative period, a more or less constant pattern for all the patients appeared from the intermittent arterial sampling. Initial pH values were usually low, the lowest being 7.25, but they showed a steady rise, so that most were normal by 3 hours and all were within the range of normal by 6 hours. The carbon dioxide contents initially were elevated and remained so during the sampling period. The carbon dioxide pressure likewise was initially elevated but showed a tendency to fall during the sampling period. The over-all picture was one of mild respiratory acidosis.

Thus, postoperative respiratory acidosis, comparable to that reported in patients undergoing thoracotomy for procedures not involving perfusion, may occur, but it is mild and of short duration. The changes may be widespread, localized, or focal in distribution, and they may occur in any part of the small or the large intestine and occasionally in the stomach. Superficial inflammatory exudation was not a constant finding, although in many patients it did constitute a distinct pseudomembrane. Concerning the causation and pathogenesis of the disease, the authors were unable to confirm the concept that a vasomotor disturbance associated with shock may be a causal condition. Before ascribing a causative significance to antibiotics, it should be noted that necrotizing enterocolitis was recognized, particularly as a postoperative complication, for many decades before their introduction. The hypothesis that necrotizing enterocolitis is directly due to infection of the intestine by enterotoxin-producing strains of Staphylococcus pyogenes var. aureus must be regarded as unproved, and there is considerable circumstantial evidence against the acceptance of this concept. Staphylococcic enteritis and acute necrotizing enterocolitis are probably not directly related, although they may occur together. Attention should be paid to the possibility that other bacteria, such as varieties of Clostridium welchii, might be the cause of acute necrotizing enterocolitis; the possibility that the disease may be due to a virus infection should also be considered. In the postoperative cases the clinical diagnosis between acute necrotizing enterocolitis and high obstruction of the small intestine is difficult; immediate laparotomy is, therefore, advised. Treatment for shock and the administration of erythromycin and adrenal hormones have so far proved ineffective.

Internal-Mammary-Artery Ligation for Angina Pectoris: Its Failure to Produce Relief. R. G. Fish, T. F. Crymes and M. G. Lovell. New England J. Med. 259:418-420 (Aug. 28) 1958 [Boston].

The authors report on the results of bilateral internal mammary artery ligation in a group of 24 selected patients with moderate or severe angina pectoris. All the patients were males, ranging in age from 32 to 64 years. In 22 patients the diagnosis of angina pectoris was made on the basis of a classic history, with transient electrocardiographic ST-segment or T-wave changes accompanying pain, or electrocardiographically proved transmural myocardial infarction at some time in the past. The character, duration, and progression of pain, requirements of glyceryl trinitrate (nitroglycerin), exercise tolerance, and occupational history were carefully noted. Eleven patients (46%) had previous transmural myocardial infarction; 10 (42%) had angina decubitus on admission. In 20 of the 24 patients on whom internal mammary artery ligation was performed, there was an initial marked improvement in the immediate postoperative period, which lasted for approximately 10 to 60 days. This period of improvement was marked by electrocardiographic stability, an increased exercise tolerance, and a reduction in the quantity of glyceryl trinitrate required. This improvement was particularly dramatic in patients who entered the hospital with angina decubitus and who continued to have occasional episodes of rest angina up to the time of operation—an improvement which in the light of subsequent findings is difficult to explain. Two patients died during the subsequent follow-up period, one patient succumbing 3 months after operation of bronchopneumonia complicating influenza, the other death occurring 5 months after operation as a direct result of coronary artery disease. In most of the remaining patients there was definite regression, with development of recurrent angina. The condition was such that at the time of writing there were only 4 patients who in their own opinion experienced moderate improvement and 2 who believed that they were slightly improved. In the remaining 18 patients the anginal syndrome resumed its preoperative course. Whether or not the survival time of these patients has been increased by an operation that failed to alter symptoms is an interesting speculative aspect of this and other surgical attempts to revascularize the myocardium.

Citrate Intoxication: A Clinical and Experimental Study. J. Ludbrook and V. Wynn. Brit. M. J. 2:523-528 (Aug. 30) 1958 [London].

The authors report on 3 men, between the ages of 24 and 55 years, and on a 44-year-old woman who were operated on with the aid of hypothermia for the following conditions: an aortic thrombosis extending up to the level of the renal arteries (2), an aortic aneurysm situated in the region of the 11th to 12th thoracic vertebrae, and a hemangioma of the liver with associated cirrhosis. In the course of the operation the 4 patients were given infusions of citrated blood, and high plasma citrate levels occurred during the infusions. One patient died with signs attributable to citrate intoxication. These observations induced the authors to study the metabolism of the infused citrate in dogs and in normal persons. A linear relationship between the rate of infusion of citrate and the rise in plasma citrate level was observed in normal men and dogs. For each 1 mg. of citrate infused per kilogram of body weight per minute, the rise in plasma citrate level was about 20 mg. per 100 cc. in dogs and 12.5 mg. per 100 cc. in man. By using a constant infusion technique, it was shown that in dogs about 40% and in man about 20% of the infused citrate was excreted in the urine, and the remainder was metabolically destroyed. In both dog and man lowering the body temperature to 28 or 29 C (82.4 or 84.2 F) by surface cooling (hypothermia) was shown to reduce the rate of metabolic destruction of citrate by 30 to 40%.

From these findings it would seem that the infusion of citrated blood at less than 1 pt. (540 cc.) in 5 minutes in an adult is unlikely to cause a dangerous rise in the plasma citrate level, provided that the rate of citrate metabolism is not reduced. However, in metabolically abnormal patients, with liver disease or with anuria, in those whose body temperature has been rendered abnormally low, or in those with impaired liver circulation or application of clamps to the thoracic or the high abdominal aorta, the ability to clear the plasma of citrate may be so impaired as to make high plasma citrate levels a real danger. If there are good resons for suspecting that a high plasma citrate level is the cause of otherwise unexplained hypotension or cardiac arrhythmia, calcium chloride should be given. Prevention is possible in planned surgical procedures when blood may have to be given rapidly (and when one or more of the circumstances which depress the rate of clearance of citrate from the plasma are present) by having available blood collected without the use of citrate.

Surgical Treatment of Pulmonary Valvular Stenosis. J. Pliego. Gac. méd. México 88:481-505 (July) 1958 (In Spanish) [Mexico, D. F.].

Twenty-four patients with a diagnosis of congenital pulmonary valvular stenosis were observed at the Instituto Nacional de Cardiologia, of Mexico City, between 1952 and 1958. Nine patients had pure pulmonary valvular stenosis, and 15 had this malformation with interatrial communication (Fallot's trilogy). The interventricular septum was normal in all the patients. One patient died of ventricular fibrillation in the course of transventricular exploration of the pulmonary valve before valvulotomy. In the remaining 23 patients the treatment consisted of a valvulotomy, alone or with closure of the gap in the interatrial septum. In the group of patients with pure pulmonary valvular stenosis, there was no operative mortality from either transventricular or transatrial valvulotomy. One patient died one week after transatrial valvulotomy of purulent pericarditis. In the group of patients with Fallot's trilogy, there were 2 operative deaths from transatrial valvulotomy: One patient died of cerebral anoxia during extracorporeal oxygenation, and the other of arrest of the heart during hypothermia. Two other patients with Fallot's trilogy died after transventricular valvulotomy, 4 hours and 4 days, respectively, after the operation. One patient died of cerebral anoxia, and the other of acute insufficiency of the left heart. Eight patients with the pure valvular malformation and 10 with Fallot's trilogy are living, more than 4 years having elapsed since the operation.

Preoperative and postoperative clinical observations and the results of electrocardiograms and of roentgenograms of the chest and of angiography, as well as the results obtained from catheterization of the right heart, proved that the transatrial technique is far superior to the transventricular technique. In patients with pure pulmonary valvular stenosis the increase in oxygen saturation of the peripheral arterial blood was more marked after the transatrial than after the transventricular operation, and the gradient of systolic pressure between the right ventricle and the pulmonary artery was either normal or greatly improved. In patients with Fallot's trilogy the results of the operation with either technique were fair. Oxygen saturation of the peripheral blood increased from 87 to 93%. Evaluation of either technique is difficult, because the results of the operation depend on the severity of the predominant malformation, either valvular or septal. The author concludes that the ideal operation for pulmonary valvular stenosis alone or with Fallot's trilogy is transatrial valvulotomy, which permits opening of the arterial valve down to the ring or else resection of a segment of the valvular apex. Transatrial valvulotomy prevents damage to the right ventricle during the operation. *It is not followed by cardiac insufficiency or by* postoperative mortality. The systolic pressure in the ventricle becomes normal or almost normal. The systolic pressure of the pulmonary artery increases. The interatrial gap is easily closed under direct vision. In cases of Fallot's trilogy, with the lesser circulation maintained by ventricular hypertension in the presence of a small foramen ovale, the correction of the valvular condition alone results in controlling the lesser circulation. Exclusion of circulation in cases of pure pulmonary valvular stenosis should be made with the patient under hypothermia, unless there is an infundibular lesion, and in this case the extracorporeal oxygenation should be used. In cases of Fallot's trilogy, transatrial valvulotomy under extracorporeal circulation facilitates correction of both the interatrial and the septal malformations in a short time. The period of extracorporeal circulation should never exceed 8 minutes for the correction of each abnormality. Transatrial valvulotomy is indicated in all patients with pulmonary valvular stenosis or with Fallot's trilogy. The patients regain a normal status after the operation.

The Conservative Treatment of Hemangiomas in Infants and Children. H. M. Blackfield, F. A. Torrey, W. J. Morris and B. V. A. Low Beer. J. Internat. Coll. Surgeons 30:255-261 (Aug.) 1958 [Chicago].

Spontaneous involution of hemangiomas of infancy and childhood was reported in the literature as early as 1888, although it was not until the appearance of Lister's paper in 1938, in which he reported a clinical study of 97 children with involuting hemangiomas, that adequate attention was focused on this phenomenon. During the 4 years of the present study, in which the authors wished to verify the occurrence of spontaneous involution and to observe its various stages, they were impressed by the fact that the lesions in patients undergoing treatment were involuting in the same manner as the untreated ones, thereby casting serious doubt upon the effectiveness of treatment. The following classification has been devised to differentiate between the involuting and the noninvoluting type of hemangioma: (1) involuting (infants)—superficial, combined (superficial and deep), and deep; and (2) noninvoluting (adults)—port-wine stain (nevus flammeus) with or without subsequent growth, true cavernous with or without subsequent growth, and venous racemose aneurysms and arteriovenous fistulas.

When surgical treatment is forced by parental pressure and is attempted during the growing phase of the large involuting type of hemangioma, the tumor can rarely be completely excised, and growth will continue in the residual vascular tissue until the latent period is reached. If operation is delayed until involution has commenced, a more conservative excision can be accomplished, as the vascular tissue will involute spontaneously. Plastic surgical measures are necessary to remove the residual disfigurements of the large hemangioma; however, such procedures, when performed a number of years after the involution of a large hemangioma, are much simpler and less dangerous than when attempted in infancy. Radical methods of treatment that may damage or prevent the growth of normal tissues are contraindicated.

The Management of Vascular Tumors. K. L. Stephenson. J. Internat. Coll. Surgeons 30:229-248 (Aug.) 1958 [Chicago].

Until such a time as criteria are available that will permit definitive differentiation of the aggressive from the regressive angiomatous tumors, these tumors are best managed by surgical excision. Surgical excision should be undertaken at the first appearance of the tumor so far as the welfare of the patient is concerned. Excision can often be accomplished with the patient under local anesthesia or, on an outpatient basis, under brief general anesthesia. Management of these neoplasms is minimized in the event of early surgical intervention, which prevents extension and complication of the growth. In the present series no recurrence was noted after surgical excision, despite the fact that many of the patients were operated on during a period of tumor growth.

Forcible Blood and Fluid Injection into the Arterial System for Patients in Terminal States. V. P. Radushkevich. Vestnik khir. 81:15-19 (Aug.) 1958 (In Russian) [Leningrad].

The author evaluates the method of forcible blood and fluid injection developed by V. A. Negovski in the treatment of terminal cases. The method consists of injection under pressure of blood and blood substitutes into the peripheral arteries or into the ascending aorta. The author reports on 224 patients who when dying were treated by this method. The treatment was successful in 47.2% of the patients, in 29.5% the response was transient only, and in 23.1% there was no response. Twenty-four of the patients were treated by blood transfusion into the aorta; 9 of these have recovered, the transient improvement only of the remaining 15 being due to injuries which were incompatible with life. Of the 40 neurosurgical patients in severe shock, with blood pressure readings of 40 to 50 degrees of mercury column, 18 have recovered. In 11 cases of clinical death, 6 patients have recovered, and of 3 patients in the agonal state, 1 has recovered. The author advocates forcible intra-arterial blood transfusion in general surgical practice and in severe neurosurgical cases.

Intraosseous Blood and Plasma Transfusion in Children. N. P. Lapshina. Vestnik khir. 81:42-44 (Aug.) 1958 (In Russian) [Leningrad].

The author reports on intraosseous blood and plasma transfusion in 118 infants and children, whose ages ranged from birth to 14 years. In the majority of the cases operative shock or hemorrhage required blood transfusion. The quantity of the transfused blood and plasma varied from 30 to 200 cc. In 84 of the patients the superior tibial metaphysis was used, in 61 the inner malleolus, and in 12 the exterior condyle of the femur. The author emphasizes that in young children the sternum should not be employed for this purpose. The intraosseous administration of blood and plasma was found to be very effective as an antishock measure and is advocated by the author as the method of choice for blood transfusion in infants and in children.

Early Surgical Correction of Inguinal Hernias in Infancy and Childhood. W. B. Kiesewetter. A. M. A. J. Dis. Child. 96:362-367 (Sept.) 1958 [Chicago].

The author reports on the results of 453 inguinal herniorrhaphies: 410 (91%) of this series were in boys; 43 (9%) were in girls. The right side was involved in 41%, the left in 19%, and both sides in 40%. Although both the direct and the indirect types of inguinal hernias are possible in children as in adults, the indirect variety is the only one that is of significance, as 99.6% of the 453 inguinal herniorrhaphies reported were of that type. Two possibilities exist in the pathogenesis of indirect inguinal hernia: 1. The processus vaginalis may never go on to complete fusion. 2. A closed processus vaginalis may be wedged open by an increase in intra-abdominal pressure. In either event a communication exists between the peritoneal cavity and the inguinal-scrotal area.

The age at onset of symptoms in 130 (54%) of the 243 patients whose parents replied was 6 months or less. Twenty-four of the 453 patients were admitted to the hospital because of an incarceration;

16 of the infants were under one year of age. Six of the patients required emergency surgery as the incarceration could not be reduced. There were only 2 recurrences in the 243 patients followed up, a rate (0.8%) that compares favorably with the 5 to 10% recurrence in adults. Only 4 of the patients had even slight asymmetry between the testes. Complications from the procedure were of 3 types: wound infections (8); "collodion burns" (2); and iatrogenic cryptorchidism (2). Of the 6 courses supposedly available for the correction of inguinal herniation—permitting spontaneous resolution; aspiration in the event of hydrocele; injection of sclerosing agents; preoperative medication, elevation of the foot, and application of an ice bag to the affected area; wearing of trusses; and surgery—the latter is, in the opinion of the author, the only rational and correct method of therapy for the condition.

NEUROLOGY & PSYCHIATRY

"Sodium Chloride Plombage" Used for Prevention of Complaints After Lumbar Puncture. G. Harrer. Medizinische, no. 29/30, pp. 1132-1133 (July 26) 1958 (In German) [Stuttgart, Germany].

During the past year the author performed 136 lumbar punctures in the neurological department of the District Hospitals in Salzburg, Austria. Immediately after the puncture, 10 to 20 cc. of isotonic sodium chloride solution, depending on the amount of the removed cerebrospinal fluid, was injected into the epidural space. By this technique, drainage from the puncture point, the main cause of a patient's complaints after the puncture, was prevented. The epidural sodium chloride plombage acts as a liquid cushion, which prevents the escape of cerebrospinal fluid from the spinal space into the epidural space. The method is simple, free from risk, and may be performed without notable expenditure of time and money. Only 3 of the 136 lumbar punctures were followed by mild complaints. The same satisfactory results were obtained with 100 lumbar punctures performed according to the same method at the neurological clinic of the University in Innsbruck, Austria.

Suicidal Poisoning. F. G. Norbury. Illinois M. J. 114:99-101 (Sept.) 1958 [Chicago].

Suicidal deaths occur in the United States at the rate of 17,000 per year. Although ingestion of poisons ranks below firearms and hanging as causes of suicide, poisonings account for about 80 suicidal deaths a year in Illinois. Most suicidal attempts do not end in death, and they frequently go unreported, so that no accurate figures are available as to their incidence. Every hospital emergency room has experience with such cases; they form an important segment of emergency medical practice. Friends or relatives usually bring poisoned individuals under medical observation before death supervenes, and suicidal poisoning usually can be successfully treated. Patients who attempt suicide with barbiturates and other hypnotic drugs usually obtain these drugs on prescription. These patients often make the rounds of several physicians and clinics and accumulate several prescriptions before the attempt is made. With the recent increasing popularity of newer sedatives and ataractic drugs, suicide attempts with these products will occur more frequently. Attempts have been reported with glutethimide (Doriden), meprobamate (Miltown, Equanil), and chlorpromazine (Thorazine).

Because suicide attempts so frequently involve the use of prescription drugs, the medical profession must bear some of the responsibility for their prevention. The possibilities of a suicidal trend should be considered in patients whose symptoms are of an emotional nature or are vague. Evidences of depression, impulsive behavior, obsession with insomnia, deficiencies in judgment, and alcoholism are all signs that should lead to wariness in prescribing large doses of sedatives. Care in prescribing involves limitations on amount and on refills. The patient-physician relationship may be a powerful factor in suicide prevention. Patients often welcome the chance to talk about their depression and suicidal thoughts if the opportunity is offered them by the physician. When suicidal trends are suspected, it is imperative to inform a member of the family of the risk, and it may be necessary to have the family control the supply of drugs. The method of attempted suicide may offer clews to the personality of the patient and act as a guide to therapy.

Aneurysms of the Middle Cerebral Artery: A Report on 52 Cases. G. af Björkensten and H. Troup. Acta chir. scandinav. 115:153-159 (No. 3) 1958 (In English) [Stockholm].

During the years from 1937 to 1956, 184 patients with intracranial aneurysms were admitted to the department of neuro-surgery of the Finnish Red Cross Hospital in Helsinki. Of the 184 patients, 52 had aneurysms of the middle cerebral artery, 27 of which were on the left side and 21 on the right. Two patients had bilateral aneurysms. One patient had aneurysms of the right middle cerebral and left pericallosal arteries, and another had bilateral middle cerebral aneurysms with a third aneurysm of the left pericallosal artery. Thirty-five of the patients were subjected to surgery—carotid ligature was not done in any instance—and the remaining 17 patients were treated conservatively. Fifty-one of the patients had shown the typical clinical picture of subarachnoid hemorrhage, and this finding was confirmed by lumbar puncture in 43. Eighteen patients had no focal neurological signs; 22 patients were or had been at one time hemiplegic or hemiparetic; and in 2 patients (1 of whom was hemiplegic), who exhibited hemianopsia, a temporal expansion was found at angiography. In all 23 patients with focal signs the aneurysm was found on the contralateral side. Approximately half of the patients exhibited definite lateralizing signs. Of the 17 patients treated conservatively, 9 died of recurrent hemorrhage at the following intervals: 3 within 10 days, another 3 within a month, 1 at 4½ months, and 2 over 2 and 3 years, respectively, after the initial hemorrhage. One patient survived, severely disabled for 2½ years, but with no symptoms of recurrent hemorrhage, only to die of cancer of the lung.

Four (11%) of the 35 patients operated on died. Postoperative angiograms performed on 21 of the 31 surviving patients revealed that in 11 cases there was no filling of the aneurysm, in 5 the aneurysm was still filling, and in 5 others the aneurysm was in much the same condition as it was preoperatively. No patient surviving operation has died, nor have any had symptoms suggestive of recurrent subarachnoid hemorrhage. In 7 patients there was hemiparesis or hemiplegia preoperatively, and in 3 more it was noted immediately after operation, while 1 other patient developed hemiplegia 15 days after operation. Only one patient in the entire group was hypertensive, although all the patients were over 40 years of age. Of those patients who had epilepsy preoperatively, 1 died, while the other 2 have been controlled by antiepileptic medication. Of the 7 who had epileptic seizures postoperatively, 6 had electroencephalographic foci in the corresponding frontotemporal region, and 1 had generalized epileptic dysrhythmia. The authors draw attention to the advisability of prophylactic epileptic therapy and suggest that hypothermia will prove particularly valuable in this type of aneurysm in which, for anatomic reasons, complications will perhaps always be more frequent than in aneurysms in other locations.

Transillumination of the Infant Head Demonstrated by a Case of Hydranencephaly. J. Griffiths. South African M. J. 32:773-774 (Aug. 2) 1958 [Cape Town].

Transillumination of the infant head is a sign deserving of greater prominence, inasmuch as it is simple to elicit and requires only a darkened room and a source of illumination—a pocket torch has been used with success. Normally, and where the cerebral cortex is more than 1 cm. thick, the test is negative, and the head does not transilluminate. When hydranencephaly is present or when the cerebral cortex is very thin, a light placed behind the head in a darkened room will light up the entire head with an orange-red light, giving an appearance rather like a Chinese lantern. The vessels of the scalp and the basal structures of the brain stand out in dark contrast to the reddish glow of light through the brain.

The transillumination test was negative in one infant with an enlarged head, and upon admission to hospital it was determined that the baby was an early and suitable case for operation. A second infant showed a strikingly positive test. The patient —believed to be the first reported case of hydranencephaly in a South African Bantu—was a plump infant with a large head measuring 19½ in. in circumference. An electroencephalogram showed little or no electric activity on the left side; on the right, however, high-voltage delta activity was recorded. Five months later the child had shown no neurological improvement, irritability had increased, and the head had enlarged to a circumference of 22½ in.

Paragonimiasis of Central Nervous System: Observations on 76 Cases. Y. C. Shih, Y. H. Ch'en and Y. C. Chang. Chinese M. J. 77:10-19 (July) 1958 (In English) [Peking].

The authors report on 1 female and 75 male patients with paragonimiasis of the central nervous system, who were admitted to the neurological service of the First Medical College in Shanghai between 1951 and 1955. Paragonimiasis is a parasitic disease caused by the lung fluke, Paragonimus westermani. The lung was involved in all 76 patients, who had cough, hemoptysis, and chest pain. The brain was involved in 71 patients, whose symptoms consisted of headache, epileptic seizures, and motor disability. The site of predilection was the temporal lobe. The spinal cord was involved in 8 patients, 3 of whom also had involvement of the brain. Of 69 patients subjected to roentgen-ray examination of the skull, only 9 showed abnormal findings, with osteoporotic lesions in the dorsal region of the sella turcica and enlargement of the hypophysial fossa, indicating increased cranial pressure. Two patients had a discernible side-to-side shift of the calcified pineal gland. Pneumoencephalographic studies revealed evidences of a mass-occupying lesion mixed with various degrees of brain atrophy in many patients. While pneumoencephalography was of great diagnostic importance, cerebral angiography was of little aid in the diagnosis of the disease.

Thirty-one of the 76 patients were subjected to 33 operations. Complete resection of the lesion was performed in 12 patients, and an adult worm was found in 8 of these; in 2 of 12 patients in whom partial resection was done, an adult worm was detected. Four patients died in the immediate postoperative period, and 2 others died after 6 months and 1 year, respectively, the causes of death being apparently unrelated to the operation. Of the 25 surviving patients, 14 were well without much handicap, 3 had occasional epileptic attacks, and 8 were seriously crippled. Of the 40 patients not operated on because of relative mildness of clinical symptoms, inability to localize the lesion, or wide spread of brain atrophy, 2 died. Of the 38 surviving patients, 7 were markedly disabled, 6 had repeated epileptic attacks, and 25 had headache, impairment of vision, or some other neurological symptoms.

Adult worms were found in 15 (40.5%) of 37 patients either in the course of the surgical intervention or at autopsy. These findings support the concept that involvement of the central nervous system by paragonimiasis is due to direct invasion by the worm rather than to egg embolism for which no evidence was found. The authors agree with other workers that an adult worm is able to migrate within the host, and they believe that, in case of brain involvement, the path of entry of the worm is through the carotid canal. The anatomic proximity of the carotid canal to the basal portion of the temporal lobe, the site of predilection of the brain lesion, is emphasized. All the patients had 3 or 4 courses of emetine and chloroquine therapy before they were operated on; yet, in their brains living worms were still present. Hence, to remove the worms and, thus, protect the nerve tissue from further damage, surgical treatment is required. Surgical treatment is contraindicated in patients with focal or diffuse brain atrophy, in those in whom the disease focus is so extensive that complete resection is impossible, and in the acute meningoencephalitic stage of the disease.

GYNECOLOGY & OBSTETRICS

The Stein-Leventhal Syndrome: A Curable Form of Sterility. I. F. Stein Sr. New England J. Med. 259:420-423 (Aug. 28) 1958 [Boston].

The Stein-Leventhal syndrome consists of a history of secondary amenorrhea and sterility, the finding of bilateral and symmetrically enlarged ovaries, and the excretion of normal amounts of 17-ketosteroids and follicle-stimulating hormone in the urine. In approximately 30% of the patients there is a varying degree of hirsutism; there is no virilism. The breasts are smaller than normal in 50% of the patients, and there is uterine hypoplasia in 75%. The direct diagnosis of the Stein-Leventhal syndrome rests upon the history and upon physical and pelvic findings corroborated by or first revealed by one of the following visual methods of diagnosis: (1) gynecography (pneumoroentgenography); (2) culdoscopy; (3) colpotomy; and (4) laparotomy.

Trials in patients with the Stein-Leventhal syndrome with endocrine therapy, roentgenotherapy, and no treatment at all have failed to result in permanently restored reproductive function. By proper wedge resection more than 85% of the patients in the author's series have been rendered ovulatory, as proved by the occurrence of pregnancy, and the fertility has been maintained throughout the woman's normal reproductive span. The operation is essentially one of decompression of the ovaries rather than the removal of ovarian tissue. In all probability simple incision and puncture or multiple punctures alone may render a favorable result. Seventy-one of 96 patients were included in follow-up studies, from the standpoint of fertility, with the following results: 1. Sixty-three patients (88.7%) became pregnant one or more times. 2. One hundred forty-three pregnancies resulted, with 119 live births, including 4 sets of twins. 3. Two patients were undelivered at the time of this report. 4. Twenty-four patients had either miscarriages or stillbirths. In this series there were no ectopic pregnancies, no carcinoma of the endometrium, and no recurrence of bilateral polycystic ovaries. Although menses were restored in 95% of the women after surgical resection of the ovaries, one patient was amenorrheic for an entire year; she then began to menstruate spontaneously and has continued to do so regularly. Selectivity of patients for wedge resection is of prime importance. Neither the complaint of sterility nor amenorrhea alone is sufficient basis in itself to justify surgical intervention.

Carcinoma of the Cervical Stump. J. C. Ullery and B. V. Bisca. Am. J. Surg. 96:360-364 (Sept.) 1958 [New York].

Despite the low mortality and morbidity of total hysterectomy today, the incidence of carcinoma of the cervical stump after supracervical or subtotal hysterectomy remains practically unchanged from that of 10 or 15 years ago. During the past 18 years 82 patients with cancer of the cervical stump have been seen among a total of 1,027 patients treated for cervical cancer. Of these 82 cases, 58 (70.7%) were "true" cases and 24 (29.3%) were "coincident" cases of carcinoma of the cervical stump, the "coincident" cases being defined as those in which the diagnosis was made within 2 years from the time of supracervical hysterectomy, and it was interpreted that cancer existed at the time of the original operation. If the malignant lesion was manifested after that time, it was listed as a "true" case and was presumed to have developed after the operation. Thus, in nearly one-third of the cases in which the diagnosis of cervical stump carcinoma was established, the malignancy was present when the initial operation was performed.

The ages of the 82 patients ranged from 32 to 78 years, with a mean average of 52 years. Thirty (36.6%) of the 82 patients had never been pregnant. The latter figure is surprising, as parity has seemed to have more than a casual relationship to cervical carcinoma. The ages at which the nulliparous patients had their supravaginal hysterectomies performed varied from 18 to 52 years, and 10 of the nulliparous patients had undergone subtotal hysterectomy before the age of 30, which may help to explain the low fertility of the entire group but leaves unexplained the indications for subtotal hysterectomy in this age group. The majority of the subtotal hysterectomies were performed for uterine fibroids. More than one-half (49) of the patients classified (International Classification) fell into the stage 2 and stage 3 categories, showing the degree to which the cancer had progressed beyond the limits of the cervix by the time the patient had made her initial visit to the clinic. Only 5 of the stage 2 patients have survived, 3 of them for 5 years or more. Each of the 3 is living with disease, complicated by rectovaginal fistula in the first and third patients and by colostomy and chordotomy in the second. Only 1 of the 11 patients with stage 4 cancer is living 4 years after treatment and with disease complicated by colostomy and chordotomy. The total 5-year survival rate for the 82 patients has been 35%.

The therapy given to the 82 patients was basically radiation, consisting of either radium or radiocobalt (Co^{60}) administered intravaginally and usually followed by external radiation; several patients received Co^{60} intracervically. In recent years selected patients have received intravaginally administered Co^{60}, followed by radical cervicectomy and bilateral pelvic lymph-node excision. When hysterectomy is indicated, the only operation justified is total hysterectomy, as this method offers the only absolute method of eradicating carcinoma of the cervical stump. In all patients on whom hysterectomy is to be performed, a thorough study of the cervix by cytological and biopsy methods and the routine dilatation and curettage of the fundus and cervical canal must be done.

PEDIATRICS

School Epidemics of Tuberculosis. R. Mande, A. Herrault, P. Loubry and C. Bouchet. Semaine hôp. Paris 34:1837-1842 (June-July) 1958 (In French) [Paris].

Epidemics of tuberculosis have changed greatly in recent years. Infection occurs at a much higher age than before, and tuberculosis has become rare in small children except in cases of direct family contamination. In contrast to this general tendency, collective contamination of children in schools has become more common and often has such an explosive spread that these group infections have been called "school epidemics of tuberculosis." These collective school epidemics have increased in recent years in France. From the epidemiologic point of view this fact is not surprising. The epidemic spread of tuberculosis is only possible if most of the population concerned has never been exposed to Mycobacterium tuberculosis, and this is now largely true of children of school age in France. Tuberculosis in school epidemics is characterized by the appearance of the disease in an unusually large number of children, by the relatively short time within which the cases occur (an average of 8 weeks), and by the frequency of severe forms. It is to be noted that no instance of collective contamination was observed when the children in a school had been vaccinated with BCG.

The origin of the tuberculous infection was established in 19 of 25 school epidemics studied by the authors. In 10 of these outbreaks, it could be traced to the teacher, in 8 to a pupil, and in 1 to a member of the auxiliary personnel. The knowledge that group contamination may occur in schools makes regular examination of both pupils and members of the teaching staff essential.

Study of the Medullary Iron in the Course of Acute Rheumatic Fever in Children. M. Bernheim, C. Mouriquand and D. Germain. Semaine hôp. Paris 34:1813-1871 (June-July) 1958 (In French) [Paris].

This study of medullary iron in patients with acute rheumatic fever is based on 119 myelograms obtained from 87 children, ranging in age from 5 to 15 years. The acute stage of rheumatic fever is marked by a fall in the number of sideroblasts, contrasting with an increase in extraerythroblastic iron, which is often considerable. Normalization of the medullary iron level occurs when the inflammatory process subsides, either spontaneously or, even more often, as a result of therapy. The changes observed in the present series were particularly distinct in the initial stage of the disease, i. e., the first 10 days after the onset of the articular manifestations. The restoration of the medullary iron to normal was found in 46 myelograms obtained after treatment with deltacortisone or hydrocortisone, given in the usual doses, for from 1 to 8 weeks. The sideroblast level was equal to or higher than 20% in 39 of the 46 patients (84.8%). The extracellular iron was considerably reduced: in 34 patients it was normal (0 to 1+); in 10, 2+; and in 2, 3+, which was the highest level observed.

The significance of these changes in the medullary iron becomes clear in the light of studies by many workers on iron metabolism in the course of infection. These studies show that in the presence of inflammation iron is blocked in the reticuloendothelial system; it is turned aside from its normal end, which is hematopoiesis. Cytological studies of medullary iron by the prussian blue reaction have illustrated this phenomenon in patients with acute rheumatic fever, showing that iron cannot penetrate into the interior of the erythroblast in the acute stage of the disease and that, therefore, it accumulates in the reticular cells of the marrow. Normal utilization of iron is restored when the inflammatory process disappears.

The rapid normalization of medullary iron under the influence of corticoid therapy brings up the question of corticoid hormone intervention in iron metabolism. Recent studies seem to show that the principal action of the corticoid hormones is to facilitate iron absorption by the cells able to use them. According to this, corticoid therapy would act directly on the sideroblastic changes. In any case, the rapid suppression of the inflammatory process remains the primary factor in the normalization of medullary iron. Comparison of the level of medullary iron with that observed in the course of experimental acute scurvy reveals a striking similarity and suggests that the changes in patients with acute rheumatic fever may be explained by a decrease in ascorbemia. The possibility that there is a relation between vitamin C deficiency and rheumatic fever has already been mentioned by several workers.

Septicemia of the Newborn. W. L. Nyhan and M. D. Fousek. Pediatrics 22:268-278 (Aug.) 1958 [Springfield, Ill.].

The authors reviewed the records of all infants, less than 30 days of age, who were admitted to the pediatric service of the Grace-New Haven Community Hospital in New Haven, Conn., between January, 1933, and July, 1957, and from whom positive blood cultures were obtained. From these patients 70 boys and 36 girls were selected, in whom a diagnosis of neonatal septicemia was made according to Silverman and Homan's criteria for sepsis of obscure origin in the newborn infant. Males predominated in a ratio of 2 to 1. The mean age at onset was 9.6 days. Twenty-five of the 106 patients were less than 48 hours of age at onset. The results of blood cultures showed that the distribution of causative agents in recent years differed from that observed before 1944. During the period from 1933 to 1943 the beta-hemolytic, group A, streptococci were predominant infecting organisms, while between 1944 and 1957 infections with coliform organisms were the most common, although group A streptococcic infections continued to occur. Significant numbers of those patients observed in the last 15 years were found to be infected with Pseudomonas aeruginosa and with beta-hemolytic streptococci of groups other than A. Fever, abdominal distention, jaundice, and enlargement of the liver were the most common clinical manifestations suggesting sepsis. However, in most patients the clinical picture was one of general, rather vague systemic illness. The serious nature of neonatal septicemia and the difficulty of early diagnosis were emphasized by the over-all mortality rate of 72% (76 of the 106 patients).

Rapid institution of antibacterial therapy is essential, for infants with septicemia often die before definitive bacteriological results of blood cultures are available. Vigorous search for the infecting organism is imperative; if the infecting organism is known at the time of instituting therapy, the choice of the antibiotic is simplified. The drug of choice in patients with streptococcic and pneumococcic sepsis is penicillin; patients infected with coliform organisms are best treated with a broad-spectrum antibiotic, such as chloramphenicol or a tetracycline, with or without additional administration of streptomycin. For the initial treatment of severe staphylococcic infections, a combination of either chloramphenicol or erythromycin with a bactericidal drug, such as penicillin or streptomycin, would appear to be indicated. The general resistance of Ps. aeruginosa to most antibacterial agents is such that in the presence of this organism the use of polymyxin B combined with a broad-spectrum antibiotic would appear to be justified for initial therapy. The use of relatively large doses in initial antibiotic therapy is suggested by the rapidly fatal nature of the disease and the frequency of infection with resistant strains. Intensive therapy should be continued until the patient is free of signs and symptoms of infection and blood cultures are negative.

Eczema Vaccinatum. A. H. Reynolds and H. A. Joos. Pediatrics 22:259-267 (Aug.) 1958 [Springfield, Ill.].

The authors report the cases of 8 boys and 1 girl, between the ages of 2 months and 4 years, who were admitted to the Children's Hospital of Los Angeles with eczema vaccinatum. In only one of the children was the condition a complication to direct smallpox vaccination; in the others it was the result of contact between a child with atopic eczema and a recently vaccinated child, usually a sibling. Suddenly appearing umbilicated pustules and vesicles, limited in distribution to areas of atopic eczema on which they are superimposed, in an acutely ill child with fever and lymphadenopathy, are almost diagnostic of eczema vaccinatum or eczema herpeticum. Umbilicated lesions do not occur with mere secondary bacterial infection. Eczema herpeticum cannot be reliably distinguished from eczema vaccinatum by the character and distribution of the lesions or by the course of the illness. History of direct contact with a recent vaccination (3 to 21 days) or with a recent typical infection of herpes simplex is strong presumptive evidence for the specific cause. Hyperimmune vaccinia gamma globulin is now available for specific therapy. In the authors' series it was given intramuscularly in doses of 0.6 to 1 cc. per kilogram of body weight. Two of the 9 patients died. The others recovered without further complications, except one patient who suffered significant scarring of the face and resolved iridokeratitis.

Because of the serious nature of eczema vaccinatum the following steps are recommended for prophylaxis: 1. No child with atopic eczema or other skin disease should be vaccinated. 2. No child should be vaccinated if any member of his family has eczema or other skin disorder. 3. Parents of children with eczema should be notified at the onset of the disease of the danger from vaccination contact. 4. If a sibling of a child with atopic eczema is vaccinated, he must be completely separated from that child for at least 21 days. 5. Forms used by state and local health departments for parents' consent to vaccination should include an appropriate warning of the contraindications. 6. Eczema vaccinatum should be a reportable disease. 7. Patients recently vaccinated must be excluded from pediatric wards containing patients with atopic eczema, other diseases of the skin, burns, or healing surgical incisions. 8. Vaccination may be recommended at 2 months of age, especially for babies from strongly allergic families.

Clinical Signs of Neonatal Tetany: With Especial Reference to Their Occurrence in Newborn Babies of Diabetic Mothers. W. S. Craig. Pediatrics 22: 297-308 (Aug.) 1958 [Springfield, Ill.].

The author describes the occurrence of hypocalcemic tetany in 7 newborn infants. All the babies were born prematurely, 6 of them to mothers with a history of diabetes mellitus. The mother of the 7th infant was obese and had a prediabetic type of glucose tolerance curve. Clinical signs of tetany appeared within 24 hours of birth. They were severe in 5 infants and mild in 2. Significantly low concentrations of calcium were determined in the serums obtained from the 5 infants with severe clinical manifestations of tetany; the lowest value observed was 2.6 mg. per 100 cc. In the 2 babies with mild clinical tetany the concentrations of calcium in the serum were also low but less dramatically so than in the more severely affected infants.

In discussing differential diagnosis of tetanic from nontetanic convulsions, clinical signs related to the presence of hyaline membrane, hypoglycemia, intracranial injury, and meningitis are considered. An observation of value is that in newborn babies, in whom hyaline membrane is later demonstrated at autopsy, respiratory embarrassment is detectable within about one hour of birth. In this series respiratory distress, occurring as part of the tetanic syndrome, did not appear at the earliest until some 6 to 12 hours after birth. The respiratory embarrassment in the infants with tetany was intermittent and lacked the insidious deterioration seen in premature babies with extensive hyaline membrane formation. Low concentrations of sugar in the blood were observed in only 1 of the 7 infants. In many respects the abnormal signs attributed by earlier workers to hypoglycemia resembled those associated with hypocalcemia in the 7 children.

The differential diagnosis of tetany from cerebral disturbance due to stress of birth is not always easy, and the 2 conditions may occur simultaneously in the same infant. In none of the infants did the circumstances of delivery suggest that the infant had been subjected to excessive or unusual stress, except insofar as all the infants with tetany were premature. Features of the hyperactive phases seen in the babies with tetany, distinguishing these phases from convulsions due to intracranial trauma, were their frequent onset in the absence of stimuli and immediately after a sudden apneic attack, the development of generalized neuromuscular excitability with no rhythmic movement pattern, and the expulsion of small masses of meconium. An unnatural quietness and almost absolute stillness followed periods of generalized neuromuscular agitation; this sudden change from wild excitability to silent immobility was not seen in any other neonatal condition. The possibility of intracranial infection was confidently excluded, since in each infant recovery was rapid and complete in the absence of antibiotic therapy.

Hypocalcemic tetany probably occurs with a significant frequency in babies newly born to mothers with diabetes mellitus. The occurrence of hypocalcemic tetany apparently is favored by the temporary decline which normally occurs soon after birth in the concentration of calcium in the serum, more particularly in premature babies. The disturbance of the normal maternal hormonal adjustments to pregnancy, and especially of adrenopituitary function in diabetic mothers, may be a determining factor.

Treatment of Tuberculous Meningitis of Children with the Exclusion of the Subarachnoid Method of Therapy. A. N. Shvedova. Pediatriya 36:23-25 (Aug.) 1958 (In Russian) [Moscow].

Shvedova reports on 32 children with tuberculous meningitis, who were treated with phtivazid (a vanilyl derivative of isoniazid) and with PAS by mouth and with streptomycin given intramuscularly. The drugs were not given by the subarachnoidal route. The improvement in the general state of the patients took place at an earlier date than it did in the children previously treated by the subarachnoidal route. The intoxication decreased, the temperature returned to normal, the meningeal symptoms disappeared, and the cerebrospinal fluid returned to normal. There were no complications.

Hyperthyroidism in Children. J. S. Hyde, M. A. Halpin and I. P. Bronstein. Illinois M. J. 114:45-51 (Aug.) 1958 [Chicago].

The authors report on 10 girls and 1 boy with hyperthyroidism, who were between the ages of 3 and 12 years at the time of onset of symptoms and were treated at the pediatric endocrinology clinic of the University of Illinois College of Medicine. Diagnosis was unequivocal in every patient, although the severity and symptomatology varied. All the patients had an enlarged thyroid gland and the characteristic cardiovascular manifestations of rapid bounding pulse and wide pulse pressure. All but one patient had eye signs, varying from separation of the eyelids to frank proptosis. Confirmation of the diagnosis had been obtained with radioiodine (I^{131}) uptakes since 1950 and in more recent years with determinations of serum protein-bound iodine. Elevated values of serum protein-bound iodine of 9 to more than 20 mcg. per 100 cc. were seen.

Either propylthiouracil or methimazole was used in treating these patients. The starting dose of propylthiouracil for young children should be 50 mg. every 8 hours. For adolescents it ranges up to 100 mg. every 8 hours. The dose of methimazole is about one-tenth that of propylthiouracil. The patients were kept in the hospital under mild sedation until improvement occurred—usually within 3 weeks. However, a completely euthyroid status was usually not achieved for 2 to 4 months. The subsequent assessment of the thyroid status was based on clinical appraisal, and the dosage was regulated accordingly. Occasionally, over 500 mg. of propylthiouracil had to be given daily to arrest thyroid activity. Maintenance treatment, with doses reduced to one-half or one-third, was continued for 6 months after the euthyroid status had been achieved to prevent recurrence. Three of the 11 patients in this series are still being treated with propylthiouracil. All are clinically euthyroid but require daily doses of 350 to 450 mg. of the drug to maintain remission. Their I^{131} uptakes 6 months prior to the time of writing, and after discontinuance of therapy for 1 month, were 57, 46, and 44% respectively. Some exophthalmos has persisted in the medically treated patients, but the thyroid gland has been considerably reduced in size.

If a child continues to have hyperthyroidism for more than one month despite attempts at medical control, surgery is advisable. Accordingly subtotal thyroidectomy was performed on 8 of the 11 patients in this series because of nodulation of the thyroid, toxic reactions to the antithyroid drugs, failure to maintain the euthyroid state on an outpatient basis, or inability to maintain adequate supervision of the patient after discharge from the hospital. Of the 8 patients operated on, 6 are now euthyroid; 1, however, has mild hyperthyroidism and 1 has recurrent toxic states and is currently receiving I^{131} therapy because of great emotional instability and failure to cooperate with medical management. A second operation was necessary in 2 patients because of recurrent thyroid nodules. A long-term follow-up of patients, even after subtotal thyroidectomy, is required. Surgical and medical opinions are divided about treatment of hyperthyroidism in children. The lack of extended patient series, the relative rarity of this disorder in children, and wide variations in follow-up practices at different clinics contribute to the existing differences in point of view.

Insulin-Producing Capacity of the Pancreas of Children with Diabetes Mellitus. R. Klein, J. Marks and I. A. Mirsky. Pediatrics 22:289-296 (Aug.) 195 [Springfield, Ill.].

The authors determined the response of concentration of sugar in the blood to the oral administration of 50 mg. per kilogram of body weight of tolbutamide and 2 Gm. per square meter of estimated body surface of indole-3-acetic acid in 12 children with diabetes mellitus and in children without evidence of metabolic disorder. These drugs are insulin-dependent hypoglycemic agents. Of the 120 children, 39 were studied during their initial hospitalization within 3 months after the diagnosis of diabetes mellitus had been made; 33 children had had clinical diabetes mellitus for 6 to 24 months, 23 had had it for 24 to 48 months, and 25 had had evident disease for 48 months or more. The administration of tolbutamide to nondiabetic children resulted in a decrease in the concentration of sugar in the blood to 56 ± 5.8% of the initial concentration within 30 minutes; the concentration of sugar increased slightly by the second hour and then remained at a hypoglycemic level for the next 3 hours. The nondiabetic children given indole-3-acetic acid did not show statistically significant changes in concentration of sugar in the blood. The administration of either tolbutamide or indole-3-acetic acid to the children whose metabolic derangement was discovered at or shortly before the time of admission resulted in a marked, statistically significant hypoglycemic response to about 70% of the initial concentration of sugar in the blood. A similar statistically significant decrease in the concentration of sugar in the blood was observed in the children with diabetes mellitus of 6 to 24 months' duration who were given indole-3-acetic acid. The children with diabetes mellitus of 24 or more months' duration showed less or no hypoglycemic response to the standard dose of either agent.

Since children with diabetes of recent origin do respond to these insulin-dependent hypoglycemic agents, it is postulated that the pancreas is capable of secreting insulin early in the course of diabetes in young persons. This ability is gradually and steadily lost, so that children with diabetes of over 2 years' duration are almost uniformly unresponsive to these 2 hypoglycemic agents. The data suggest that, after a variable period of clinically evident diabetes mellitus, the pancreas of the child becomes exhausted and incapable of secreting insulin.

Theoretical and Practical Questions on Chromosomal Sex Determination. E. Zdansky. Ann. paediat. 191:26-49 (July) 1958 (In German) [Basel, Switzerland].

Some investigators of chromosomal sex determination suggested that the sexual differences in the sex chromatin are caused by the differences in the size of the heterochromatic portions of the sex chromosome complexes of the nuclei of the somatic cells in females and males. Whereas the heterochromatic portions of 1 X-chromosome alone or of 1 X-chromosome and 1 Y-chromosome together are not large enough to be differentiable from the remainder of the chromatin, the female XX-complex is just large enough to be recognized as the "sex chromatin." Some observers cited as proof of this assertion the observation that the ovulum in the human ovary, which contains only 1 X-chromosome, has no sex chromatin but the surrounding follicular cells do have the sex chromatin. Considered from this viewpoint, the sex chromatin is really the conglobation of the heterochromatic compact portions of the 2 X-chromosomes of the cellular nucleus in the female organism. The male X-Y complex, which under normal conditions is too small to be differentiable from the remaining chromatin, becomes evident during chromatolysis. This fact must be considered during the practical evaluation of this sexual differentiation.

The author discusses various methods employed in chromosomal sex determination. At least 2 methods should be used to arrive at a reliable diagnosis of the genetic sex. The methods most easily employed in a clinic are the determination of chromosomal sex from the segment-nuclear leukocytes and from the epithelial cells of the buccal mucosa. The advantages of Feulgen staining over those of cresyl-violet staining are pointed out. Chromosomal sex determination is of particular importance in problems of intersexuality and in persons with deformities of the genitalia. The results obtained in persons with such abnormalities raised the question whether the sex chromatin is influenced by genetic, endocrine, or other factors. In this connection the author gives particular attention to the "drumstick" form of the sex chromatin in the leukocytes. If endocrine or other factors seem to exert an influence on the sex chromatin, they do this only indirectly by way of the nuclear morphology, because the influence becomes apparent only in the nuclei of the neutrophil leukocytes, not in the nuclei of the mucosal epithelium.

Meningeal Hemorrhages of Weak and Premature Infants: New Anatomicoclinical Investigations. P. Giraud, J. Espinas, J. Coignet and P. Decoppet. Semaine hôp. Paris 34:1817-1830 (June-July) 1958 (In French) [Paris].

Meningeal hemorrhage is a frequent cause of mortality during the first days of life in weak and premature infants. It was observed in 75 (15%) of 500 infants weighing less than 2,000 gm. (4½ lb.), who were admitted to the Centre Hospitalier for weak and premature infants at Marseilles, during the last 5 years. Meningeal hemorrhage was responsible for 51 of the 100 deaths due to known causes, and of the infants in whom this complication occurred, 70% died. Autopsy findings in 59 cases showed that meningeal hemorrhage is not caused by rupture of the large vessels or by lacerations of the dura mater but that it is the result of a slow escape of blood, often associated with edema of the central nervous system. The hemorrhage originates in the pia mater, the choroid plexuses, and the vessels of the ventricular walls. The mechanism producing this accident depends more on the degree of debility and prematurity than on obstetric trauma. The clinical signs of meningeal hemorrhage consist of respiratory disturbances, rather than of neurological disorders in the strict sense. Vasomotor disturbances, due to the inability of the vegetative system to perform its function because it is not yet fully developed, seem to be responsible for the edematous and hemorrhage-producing congestion of the nerve centers seen in the specimens. Prematurity itself, that is, the anatomic and functional underdevelopment of the nerve centers and the vegetative system, is apparently the cause of meningeal hemorrhage in the weak and premature infant. Other factors, such as trauma and anesthesia, may contribute to the fatal outcome, but the premature infant can be said in many instances to die because of the functional inadequacy of his nervous system.

Therapy should be based chiefly on careful reanimation, the administration of circulatory analeptics, coagulants, and, as adjuvants, nerve sedatives. Lumbar puncture and transfusions should be used with caution. Cortisonic remedies do not appear to have much effect on the course of the condition. Good nursing care, carried out by a well-trained nursing staff, is just as important as purely medical treatment. Preventive treatment of debility alone can diminish the frequency and severity of meningeal hemorrhage, which still contributes so extensively to infant mortality statistics during the first days of life.

A Major Clinical Entity in Pediatrics: Respiratory House-Dust Allergy. R. Mande, A. Herrault and C. Thérond. Semaine hôp. Paris 34:1843-1852 (June-July) 1958 (In French) [Paris].

Respiratory house-dust allergy, which is the most common form of respiratory allergy in the Paris region, may appear as rhinitis, rhinopharyngitis, recurrent tracheitis, bronchial asthma, or true asthma. The condition seems to be more prevalent in boys than in girls; out of 308 children with this form of allergy, 189 (61.3%) were boys. The age of the children at onset varies. Disturbances are not exceptional before the first year of life, and in 21% of the children of this series they began before the age of 6 months. Certain clinical signs, especially the appearance of the symptoms in the autumn and winter, should be sufficient to arouse suspicion of the allergic nature of the disturbance and should lead to tests with specific allergens. Intradermal tests are preferable to scarification, because they produce more distinct reactions. Examination should consist of thorough interrogation, clinical examination, a search for other allergic manifestations, especially cutaneous ones, a study of the eosinophil count, and examination of the nasal mucosa. Treatment does not consist in desensitization properly speaking, but rather in "mithridatism" or hyposensitization. This may be produced either by giving injections of gradually increasing doses of dust extract at short intervals, or by giving extremely weak doses of dust extract at longer intervals. The second method takes longer, but it is especially suitable for children, because it is gentle and flexible. Out of 154 children so treated, 133 were definitely improved (86.4%); 18 were moderately improved (11.7%); and in 3 (1.9%) the treatment did not seem to influence the allergy. Thus, satisfactory results were obtained in more than 80%. The success of the treatment was most striking in the seriously ill patients with permanent asthma or inveterate cough, most of whom were able to resume their normal activities and school attendance. The authors emphasize the fact that, except in limited and definite instances, all rhinopharyngeal surgical interventions, such as tonsillectomy and adenoidectomy, should be avoided in allergic children, because they lead to undesirable sequelae.

UROLOGY

Long-Term Treatment of Urogenital Tuberculosis with Triple-Drug (Aminosalyl + Streptomycin + Isoniazid). C. G. Hansson. Nord. med. 60:978-979 (July 10) 1958 (In Swedish) [Stockholm].

The advantages of treatment of urogenital tuberculosis with a combination of chemotherapeutics—PAS, streptomycin, and isoniazid—that are (1) lower doses of the preparations can be applied and toxic side-effects avoided, (2) a synergetic effect results, presumably because the preparations have different points of attack on the tubercle bacilli, and (3) the development of resistant strains can be delayed or possibly prevented by the combination of therapeutics. At Rävlanda Sanatorium triple-drug treatment was given for at least a year to 25 patients (17 men and 8 women) with urogenital tuberculosis. In all cases the urine reverted to normal. The average time from the start of treatment until reversion was 2.9 months; the average time from reversion until the last guinea-pig test was 18.2 months. No relapses occurred during this time. The average time of observation from ended treatment until the last guinea-pig test was 6.2 months. Earlier experiences showed that in cases with recurrence the relapse, as a rule, appeared during the first months after ended treatment. Because of the good results of triple-drug therapy at Rävlanda, nephrectomy is performed only in cases where there is marked reduction of function in one kidney because of extensive tuberculous changes. In 12 other patients (9 men and 3 women) given triple-drug therapy for a time, one of the preparations was withdrawn on account of side-effects; however, treatment was continued with the other preparations for at least a year, with good effect. In a few patients the triple-drug treatment was not carried out for a year, as tubercle bacilli continued to be found in the urine after 6 to 8 months' treatment, and another combination was applied.

INDUSTRIAL MEDICINE

Pneumoconiosis in Iron Miners: Chemical and Histological Study. R. Even and C. Sors. J. franç. méd. et chir. thorac. 12:374-387 (No. 4) 1958 (In French) [Paris].

A partial answer to the question whether the pneumoconiosis of iron miners is a siderosis, a silicosis, or a combination of these conditions has been obtained by the chemical and histological study of autopsy specimens in 12 personal unpublished cases of pneumoconiosis. The patients were miners who had worked exclusively in iron mines and who had been exposed to the danger of pneumoconiosis for from 19 to 31 years (average, 23 years). The disease was recognized, and the patients were indemnified from 1 to 7 years before death in 7 of the 12 cases; in the other 5, the diagnosis was established only after death. The level of free silica in the lungs, which is normally 50 mg. per 100 Gm. in a fresh specimen and 250 mg. per 100 Gm. in a dry specimen, was twice or three times that amount in 6 cases, 5 of which presented evidence of silicosiderosis. Ferric oxide was also greatly increased, usually to a level 14 or 15 times the normal, in all 12 cases.

Death was caused by right ventricular insufficiency in 7 patients, pulmonary tuberculosis in 1, ordinary bronchopneumonia in 1, prostatic cancer in 1, primary bronchial cancer in 2, and various conditions in 4. Right ventricular insufficiency was the cause of death in 5 of the 6 patients who had silicosiderosis and in 2 of the 6 who had siderosis. Sclerosis, emphysema, and siderosis were constant histological findings, in contrast to silicosis which was found in only half of the specimens. The case reports and the autopsy findings in these 12 patients, as presented in this article, thus show that, contrary to the optimistic views commonly held, the pneumoconiosis of iron miners usually progresses to death as a result of right ventricular insufficiency. It should therefore be regarded as an occupational disease entitling the patient to compensation.

Pneumoconiosis from Bagasse, Cement and Agave. E. W. Baader. Bol. Asoc. méd. Puerto Rico 50:171-180 (May) 1958 (In Spanish) [Santurce].

Inhalation of the dust of bagasse, cement, and agave fibers is a frequent cause of industrial pneumoconiosis. The symptoms of bagassosis may appear as early as 8 weeks after exposure of a person to the dust. They consist of acute bronchitis and atypical pneumonia, with fever, violent cough, and hemoptysis. The disease may be fulminant, may follow a natural course to recovery of the patient, with or without respiratory sequelae, or may follow a slow course for 3 or 4 years to a fatal outcome. The disease is believed by some to be an allergy; by others it is considered a reaction of the lungs either to a foreign body or to the salicylic acid contained in bagasse. The author believes that bagassosis is a mycosis caused by fungi and spores living in bagasse. He isolated 8 strains of organisms of the Aspergillus, Rhizopus, and other genera from bagasse. The pathological condition of the lungs of rats which had been subjected to inhalation of bagasse dust consisted of a chronic inflammation and a foreign body reaction. Although there is no specific treatment for bagassosis, prevention of the disease by means of apparatus to absorb the dust in sugar factories is of value.

Contact of cement dust with the skin may produce abscesses, ulceration, eczema, and other cutaneous lesions. Working in an environment pregnant with cement dust may cause conjunctivitis, inflammation and ulceration of the buccal and nasal mucosa, and even perforation of the nasal septum. Inhalation of cement dust may cause the formation of rhinoliths and inflammation of the mucosa of the upper respiratory tract. Cement pneumoconiosis is rare. Still more rare are the severe forms of the disease progressing to a fatal outcome. Pneumoconiosis caused by the dust from fibers of the agave is more frequent than it is believed to be according to the modern literature.

The Effect of Tractor Noise on the Auditory Sensitivity of Tractor Operators. D. M. Lierle and S. N. Reger. Ann. Otol. Rhin. & Laryng. 67:372-388 (June) 1958 [St. Louis].

Little is known about the effect of tractor noise on auditory sensitivity. During a practice of otolaryngology for the past several years in a rural area, the authors observed a number of farmers with dips at 4000 cps. In some instances the ear history and the physical examination were normal, except for the probability of tractor-noise-induced hearing loss. This paper presents the results of a two-part study of the effect of tractor noise on auditory sensitivity: the first part deals with the measurement of tractor noise; the second part is concerned with the results of pure tone threshold sensitivity measurements on 80 full-time tractor operators. The authors consider the results of this preliminary study as tentative until confirmed by other auditory measurements. They note the following points: 1. Tractor noise is sufficiently high in intensity to produce high-frequency hearing losses in tractor operators with noise susceptible ears if exposed over a period of several years. 2. The intensity of tractor noise can be reduced by more effective mufflers; the noise of certain tractor attachments also can be reduced by vibration control methods. 3. Dips in high-frequency perception are more common in patients between the ages of 30 and 60 years. 4. The absence of dips in older persons does not rule out the possibility of some noise-induced hearing loss. 5. Slightly greater losses occur in left than in right ears. 6. Individuals with noise susceptible ears usually experience tinnitus; such persons should wear ear plugs while operating tractors. 7. It is recommended that hearing surveys in the future be designed to test sensitivity at 500, 1000, 2000, 3000, 4000, and 8000 cps in order to obtain more information about the frequency-intensity characteristics of dips and to learn more about the aging ear.

THERAPEUTICS

The Liberation of Morphine from Codeine in Man and Dog. P. Pærregaard. Acta pharmacol. et toxicol. 14:394-399 (No. 4) 1958 (In English) [Copenhagen].

In an attempt to answer the question whether the analgesic action of monomethyl-morphine (codeine) is due entirely or in part to conversion into morphine, experiments were carried out on 6 human volunteers and on 3 dogs. The human volunteers were given 50 mg. of codeine phosphate orally, and urine was thereafter collected over 8-hour periods. Each of the dogs was given doses of 2, 20, and 40 mg. of a preparation containing 5% codeine per kilogram of body weight in 3 successive experiments; the drug was given subcutaneously in 2 experiments and orally in 1. Urine specimens were collected for 24 hours in 2 amounts—an 8-hour fraction and a 16-hour fraction. Each urine specimen was analyzed for morphine, 1 portion before and 1 portion after hydrolysis, in order to determine both free and total morphine. About 4% of the administered amount of codeine was excreted as morphine in the urine of the human volunteers. This corresponds to a conversion into morphine of about 10% of the codeine. No measurable amounts of free morphine were found in the urine. In the dogs, about 2% of the codeine was demethylated to morphine. After the administration of the largest doses of codeine, 2 to 4% of the morphine excreted was in the free form. These findings suggest that the pharmacological action of codeine is due, at least in part, to the morphine produced. There is much evidence to suggest that the effect of the resulting morphine is considerably less than that of the same amount of morphine injected as such into the organism.

Clinical Experiences with Orisul, a Long-acting Sulfonamide Preparation. A. F. Essellier, H. Hunziker and R. Goldsand. Schweiz. med. Wchnschr. 88:813-817 (Aug. 16) 1958 (In German) [Switzerland].

The authors report on 73 patients with diseases of the genitourinary tract, 37 patients with diseases of the respiratory tract, 3 patients with diseases of the bile ducts, and 7 patients with miscellaneous conditions who were admitted to the medical clinic of the University in Zurich, Switzerland, and were treated with Orisul [3-(*p*-amino-benzolsulfonamido)-2-phenyl-pyrazol]. As a rule, the patients were given orally 1.5 Gm. of the drug per day; a few seriously ill patients were given 1.5 Gm. twice a day at intervals of 12 hours. Unconscious patients or those with a preceding intestinal disturbance were given 0.5 to 1 Gm. of the drug intramuscularly every 12 hours. The success of the therapy was evaluated according to the following criteria: restoration of temperature to normal, improvement in local findings, decreased erythrocyte sedimentation rate, and generally improved condition. The absorption, excretion, and tolerance of the drug were studied in an additional 54 patients.

Maximal concentration of Orisul in the blood was obtained within 3 or 4 hours after the oral administration of a single dose of 1.5 Gm., and after 44 hours the blood level was still 1.5 mg. per 100 cc. The degree of acetylation proved to be small, 10 to 15% appearing in the blood in the acetylated form. Orisul proved to be clinically effective in infections caused by streptococci, enterococci, pneumococci, staphylococci, Escherichia coli, and Proteus organisms. Of the 73 patients with genitourinary disturbances, 59 had chronic cystitis, 7 acute cystitis, and 7 acute cystopyelitis. Thirty-six of the patients with chronic cystitis, 4 of those with acute cystitis, and 4 of those with acute cystopyelitis were clinically cured. Of the 37 patients with diseases of the respiratory tract, 10 had bronchopneumonia, 3 had peribronchiectatic pneumonia, 9 had emphysematous bronchitis, 6 had pneumonia associated with influenza, and 7 had various pulmonary conditions. Good results were obtained with Orisul in 5 patients with bronchopneumonia, in 2 with peribronchiectatic pneumonia, in 5 with emphysematous bronchitis, and in 5 with pneumonia resulting from influenza. Temperature was restored to normal by crisis within 1 or 2 days. One patient with chronic cholecystitis and 2 patients with cholangitis made a complete recovery. Orisul proved to be effective in 3 patients with acute tonsillitis and furunculosis and in 2 patients to whom it was given prophylactically to prevent infection in the course of corticosteroid therapy. It was also clinically effective in many patients in whom the causative agents were found to be resistant in vitro to other sulfonamide preparations or to antibiotics and in whom treatment with these other drugs had been ineffective. Undesirable side-effects, such as nausea, formation of Heinz bodies, and allergic cutaneous reactions, were rare.

Use of Sulfonylurea Compounds for Treatment of Diabetes Mellitus. J. R. Hofstetter and C. Ramel. Schweiz. med. Wchnschr. 88:821-827 (Aug. 23) 1958 (In French) [Basel, Switzerland].

The authors report on 160 patients with diabetes mellitus who were given ambulatory treatment with the sulfonylurea compounds, carbutamide (BZ 55) and tolbutamide (D 860). Of the 160 patients, 152 were more than 40 years of age and 8 were less than 40. Treatment was effective in 136 patients, and 24 patients were failures. Six (75%) of the 8 patients, aged less than 40 years, were failures. Of 43 patients over 70 years of age, 1 (2.5%) was a failure. The ratio of failures thus diminished with age. The older the patients the better they responded to the treatment.

Of the 24 patients in whom the treatment failed, the duration of the disease was less than 6 months in 1 and more than 5 years in 14; thus, there were more failures among the patients with diabetes of longer duration. There were more failures also among those requiring high doses of insulin, but 6 of 14 patients requiring more than 40 units of insulin responded satisfactorily to the treatment with sulfonylurea compounds alone. The duration of previous treatment with insulin did not seem to be of great importance. Juvenile patients with diabetes mellitus and those with hemochromatosis did not, as a rule, respond to the treatment with sulfonylurea compounds. Although late failures have been reported by other workers, they were not observed by the authors. In contrast to other workers who have been able to decrease the amount of insulin administered by combining it with sulfonylurea compounds, especially in young and in hospitalized patients, the authors were not able to obtain favorable results by such a combined treatment in their ambulatory patients.

Intolerance for carbutamide was observed in 13 patients and intolerance for tolbutamide in 2; these observations confirmed those by other workers that, in general, the tolerance for tolbutamide is better than that for carbutamide. Occasionally it was possible to overcome sensitization to the drug by a progressive increase of very small doses (desensitization). Hypoglycemia, as a rule, is rare, but 1 case of severe hypoglycemia resulting in death was observed in a 63-year-old woman with adrenal cortical hypofunction (Addison's disease), who was given 3 tablets of carbutamide daily in an attempt to stimulate the patient's appetite. A definite increase in body weight, continuing for some weeks in the course of the treatment with carbutamide, was observed in several patients. The effects of carbutamide and tolbutamide were compared in 48 patients who first were treated with carbutamide and then with tolbutamide; in 34 of the 48 patients the 2 compounds were equally effective, but in the remaining 14 tolbutamide was inferior to carbutamide. Eight of the 160 patients had cirrhosis of the liver, and this complication was not influenced by treatment with the sulfonylurea compounds; these drugs did not seem to exert an effect on the vascular and infectious complications of diabetes mellitus. Carbutamide has more secondary effects than tolbutamide, but it is also more active than that drug.

Clinical Cure of Buerger's Disease with a New Treatment: Malarial Therapy. F. Corelli. Minerva med. 49:2685-2696 (July 7) 1958 (In Italian) [Turin, Italy].

During the past 17 years the author has treated 32 patients with thromboangiitis obliterans (Buerger's disease) by the intravenous administration of 30 to 50 cc. of homologous blood obtained from patients with tertian malaria during the episodes of chills. Malaria was thus induced without the incubation period, and the disease began its clinical course a few hours after the injection. First, the temperature rose from 39 C (102.2 F) to 40 C (104.0 F), accompanied by leukopenia and splenomegaly. The temperature remained constant for the first 2 to 4 days of the incidence of malaria and was followed by the typical chills of tertian malaria. Buerger's disease was clinically cured after 7 or 8 chills in a period of 10 to 15 days. The induced malaria was then cured with chloroquine, administered by the oral or the intramuscular route, within 24 hours. The general health of the patients improved remarkably a few days after they became afebrile, and no complications attributed to malarial infection developed in them. However, smoking or inhalation of the air of smoke-filled rooms proved harmful, and elimination of all contact with smoking was considered essential.

Treatment of Buerger's disease with malarial therapy can have adverse effects in patients who are simultaneously treated with either cortisone or corticotropin (ACTH). This therapy may also be harmful for patients who have undergone unilateral adrenalectomy and is contraindicated for those who have undergone bilateral adrenalectomy. The author believes that the therapeutic effect of malarial therapy for Buerger's disease is based not merely on its antipyretic properties but that this is an instance of a disease cured by induction of another disease. Malaria as a "second" disease produces systemic anti-inflammatory, analgesic, and resolvent actions.

PATHOLOGY

Studies on Division Inhibition and Filament Formation of Escherichia Coli by Ultraviolet Light. R. A. Deering. J. Bact. 76:123-130 (Aug.) 1958 [Baltimore].

The author carried out quantitative microscopic studies for determining the effect of monochromatic ultraviolet radiation on the cellular division of Escherichia coli, strain B. It was found that the division inhibition, or, more accurately, extended delay, which is produced in Esch. coli by relatively low doses of monochromatic ultraviolet radiation, is rather specific in that division stops, while total mass, ribonucleic acid, and deoxyribonucleic acid synthesis continue at nearly the same rate as for dividing cells. The nondividing cells continue to increase in length, and long filamentous cells result. The curves in which survival and retention of ability to divide are plotted against dosage of ultraviolet radiation indicate that a single hit disorganizes an entire cell. The 37% survival dose is 3 ergs per square millimeter at 2652 A ultraviolet radiation. Many of these filaments recover the ability to divide at some later time and form normal-appearing macroscopic colonies. The ultraviolet action spectrum for division inhibition suggests nucleic acid as the ultraviolet absorbing cell component active in initiating the extended delay. The division inhibition can be partially reversed by irradiation with visible light if given within 20 minutes after the completion of the dose of ultraviolet irradiation. The filaments appear to be single cells with many "nuclear bodies" and not segmented structures or chains of cells.

Metastasis of Cancer to Cancer. I. Gore and R. Barr. A. M. A. Arch. Path. 66:293-298 (Sept.) 1958 [Chicago].

Metastasis of cancer to cancer is an exceedingly rare event, considering the frequency of neoplastic disease and the not uncommon occurrence of multiple malignancies. Two such cases are reported in which widespread carcinomas, originating in breast and prostate, respectively, formed secondary deposits in localized nephromas. In view of the fact that the success or failure of secondary tumor growth is dependent upon competition with the host tumor for essential nutrients, and in view of the smaller nutritive requirements of the localized hypernephroid tumors, it is not surprising that such tumors are the recipient neoplasms in more than two-thirds of the cases inasmuch as they are one of the less frequent forms of cancer. The rarity of metastasis to cancer and the fact that the supply of nutrients is more often than not inadequate for the simultaneous growth of 2 malignant neoplasms are compatible with the tenet that the localized hypernephroid growths are dormant growths and have not as yet attained the degree of anaerobic metabolism characteristic of full-grown malignant neoplasms.

Yeast Antibiotic with Therapeutic and Prophylactic Properties. I. A. Parfentjev. J. Infect. Dis. 103:1-5 (July-Aug.) 1958 [Chicago].

The author isolated from alkaline aqueous extracts of brewer's and baker's yeast a fraction containing a protein possessing anti-infectious properties. This new agent was called Malucidin. It differs from other antibiotics in that it has a much broader spectrum of action and produces a longer lasting effect. The new antibiotic is readily soluble in water in a wide range of pH, has an isoelectric point near pH 2, and is not dialyzable. It can be precipitated in 50% ammonium sulfate and also by the addition of an equal volume of acetone; it can be precipitated easily at neutrality by 0.05 M calcium chloride or by only 0.005 M cadmium chloride. Chemotherapeutic experiments with this agent showed solid protection of mice, guinea pigs, rabbits, and pigeons against many species of gram-negative and gram-positive bacteria. Malucidin also protected mice against systemic infection with Candida albicans and against Shigella endotoxin. Peritoneal injections of Malucidin in mice induced resistance to infections with Proteus organisms which lasted one month.

Symptomatology and Pathology of Pulmonary Adenomatosis. P. Weicksel and H. Cain. Ztschr. klin. Med. 155:310-328 (No. 3) 1958 (In German) [Berlin].

The authors report on 4 women, aged 43, 54, 39, and 61 years, respectively, with pulmonary adenomatosis, on whom autopsies were performed after death. Tumors of adenomatous type in the lung may be classified in 3 basic groups: (1) those occurring in the course of diffuse, progressive, interstitial pulmonary fibrosis and cirrhosis (so-called pseudoadenomas); (2) those of congenital origin; and (3) genuine primary pulmonary tumors (pulmonary adenomatosis in the proper and narrower sense). All 4 patients had tumors of the third type. The first symptoms of the disease were refractory irritative cough and pain at the side of the involved lung. The occurrence of copious, mucous, watery-clear sputum was manifested almost simultaneously with increasing dyspnea. When pulmonary insufficiency became manifest, it dominated the clinical picture until the patient died. The primary cause of this pulmonary insufficiency is a disturbance of ventilation, since the alveoli are filled with mucus and their walls are lined with mucus-forming, high cylindrical cells. But there may also occur a disturbance due to spread and manifested by considerable reduction of the respiratory limiting values. A malignant behavior of the tumor was observed from the onset in the 39-year-old patient, with rapid destruction of parenchyma, vascular involvement, and metastases; connective tissue thickening of the interalveolar septal structures was associated with considerable restriction of the capillary surface. Prolonged duration of such changes may cause dilatation of the right heart, as it occurred in this patient, and chronic cor pulmonale may result later.

Autopsy findings showed macroscopically 2 forms of adenomatosis, i. e., focal-nodular adenomatosis and diffuse adenomatosis reminding one of lobar pneumonia. The latter form probably originates from the first by secondary spread. Microscopic findings also revealed 2 forms of adenomatosis. The cell picture of the first form was that of a completely uniform, highly differentiated adenoma which hardly had the appearance of a malignant tumor. There was no involvement of blood and lymph vessels. The pulmonary structure was preserved. Aerogenic spread to several lobes may cause respiratory insufficiency and cardiovascular decompensation, and this course is responsible for the unfavorable prognosis. The cell picture of the second form did not differ in principle from that of mucus-forming adenocarcinoma. Destruction of parenchyma resulted from perforation of the alveolar wall and infiltration of the interstitial spaces, with severe connective tissue reactions. The course of this form of the disease is rapid. An alveolar origin of the adenomatosis with an onset in a circumscribed area was assumed in all 4 patients. In contrast to Eck's concept, adenomatosis should be considered as a primary tumor-forming disease of the lung and should be differentiated from bronchial carcinoma and from secondary carcinomatous pneumonia.

RADIOLOGY

A Study of Radiation Therapy in Carcinoma of the Pancreas. J. S. Billingsley, L. G. Bartholomew and D. S. Childs. Proc. Staff Meet. Mayo Clin. 33:426-430 (Aug. 30) 1958 [Rochester, Minn.].

The diagnosis of carcinoma of the pancreatic exocrine parenchyma was established histologically in 64 cases at the Mayo Clinic in 1953. Twelve of the 64 patients are excluded from this study inasmuch as they underwent radical excision. Of the remaining 52 patients, 29 were treated with some sort of palliative operation (choledochoduodenostomy, gastroenterostomy, etc.), while 20 underwent no surgical procedure other than biopsy. Six of the surgical group received postoperative radiation therapy, as did 7 of the biopsy group. All but 1 of the 13 patients were treated with a radiocobalt (Co^{60}) teletherapy unit, the one exception being treated with a conventional 250-kv. x-ray machine. The average tumor dose was 3000 r given over an average of 19 treatment days. The authors do not consider the slight differences in the survival figures between the irradiated and the nonirradiated groups as significant. Moreover, they do not consider that radiation therapy in the doses given in this series offers the patients any appreciable chance of longevity. A review of the individual case histories in an effort to discern the presence of some of the less tangible potential benefits of radiation, such as relief of pain or retardation of the formation of fluid, was equally discouraging. The authors conclude that radiation therapy in the doses given in this series is of little or no value as a palliative measure in cases of carcinoma of the pancreas.

Tuberculomas: Criteria for Roentgenographic Differential Diagnosis. L. Oliva and G. Secondo. Minerva med. 49:2431-2440 (June 20) 1958 (In Italian) [Turin, Italy].

The authors found that, in considering roentgenologic criteria alone, stratigraphy according to the technique of Vallebona is the most useful procedure for differentiating a tuberculoma from peripheral pulmonary tumors and from other round-shaped intrapulmonary lesions. Round-shaped shadows with clear borders and with a diameter not exceeding 2 cm. indicate a tuberculoma. Other shadows with irregular and trimmed borders, as if they were caused by abrasion, cannot be related to a tuberculoma. Round-shaped, opaque shadows made of concentric layers are characteristic of a tuberculoma of the Lachman-Uehlinger type. Dense and homogeneous opacities denote a tuberculoma; nonhomogeneous opacities denote neoplastic lesions. Calcifications with nuclei located in the middle and those made of concentric layers reveal a tuberculoma. Multiple hollows in the shadow of a tuberculoma have an oblong shape and are mostly located along the periphery; multiple hollows in the shadow of a malignant tumor have various shapes and irregular disposition. Large lymph-node-like masses which compress and displace the trachea and the bronchi represent metastases of the lymph nodes. Shadows which are stationary or retrogressive in size indicate a tuberculoma, whereas shadows of a malignant tumor are erratic and do not show a uniform increase in size. The preceding observations are helpful, but they are not unequivocal indications for making a roentgenographic differential diagnosis of tuberculoma. Roentgenologic interpretations must be complemented with the clinical and laboratory findings.

PUBLIC HEALTH

Unusually High Incidence of Appendicitis Cases at Dohad Town in Panch Mahals District in Bombay State: Preliminary Communication. T. B. Patel and V. N. Rao. Indian J. M. Sc. 12:517-520 (July) 1958 (In English) [Bombay, India].

Between March and December, 1957, 64 cases of "appendicitis" were detected in 30 male and 34 female patients, all of whom except 1 were Banias and all except 2 were residing in 2 areas adjacent to the main tank in Dohad Town in Panch Mahals District in Bombay State, India. Most of the patients were between the ages of 10 and 35 years. Only 5 patients had a typical acute attack of appendicitis, with acute pain in the right iliac fossa, tenderness at McBurney's point, fever, and vomiting. In the other patients the pain was of a more chronic and general type, either being all over the abdomen or being in the right hypochondrium or epigastrium in the beginning and then later localized to the right iliac fossa. Pain was associated with fever in 18 patients and with vomiting in 23. In 56 patients the pain was of a very mild nature and became severe only before they were operated on for "appendicitis." Two of these patients died shortly after the operation; a gangrenous appendix had been found at operation in one, and the other patient was considered by the surgeon to have typhoid.

The acute onset of symptoms, with fever, pain, and vomiting, suggested an infective process. The fact that nearly all the cases occurred in the Bania community suggested a common source of infection. It was noticed that the Banias were mostly using water from the adjacent tank for washing, bathing, and sometimes cooking purposes, in addition to using water from wells located close to the tank. The tank water showed heavy pollution on bacteriological and chemical analysis. Stool examination showed that only 1 of 46 specimens was positive for Entamoeba histolytica. Fifteen blood specimens were obtained from patients operated on and were subjected to serologic examination; by slide agglutination a significant number were found to be positive for Salmonella enteritidis, Sal. typhimurium, and Sal. choleraesuis, and many specimens showed multiple infection. On examination of 13 additional serums, it was found that a significantly high proportion of the specimens obtained from those who had undergone surgery and those who had not gave positive results by tube agglutination for Shigella sonnei, Sh. flexneri, and Sh. shigae. The occurrence of cases of "appendicitis" in such large number as was revealed by this study appeared to be the outcome of a multiple Shigella-Salmonella infection, a finding which seemed to be unique in the literature.

An Epidemic of Shigella Sonnei Dysentery Arising in a General Hospital. N. J. Ehrenkranz, M. J. Takos, W. R. Hoffert and F. Reimer. New England J. Med. 259:375-377 (Aug. 21) 1958 [Boston].

In a 5-day period in July, 1957, there was an explosive outbreak of gastroenteritis involving approximately 80 persons, the majority of whom were employees of the Jackson Memorial Hospital in Miami, Fla. Eleven were patients previously hospitalized for another illness; the rest were nurses, physicians, surgeons, medical students, and clerical employees. The onset of symptoms was gradual, with headache, anorexia, and malaise preceding abdominal cramps and blood-streaked diarrhea by 8 to 12 hours. Maximum temperature in the hospitalized patients was 103.4 F by mouth; maximum duration of fever was 8 days; and total duration of diarrhea was 10 days. Microscopic examination of feces revealed many red and white blood cells. Cultures of stool and rectal-swab specimens revealed the presence of Shigella sonnei in 37 patients. One of the 2 food handlers in the cafeteria responsible for the contaminated food was disclosed to be a carrier of Sh. sonnei. Epidemiologic evidence pointed to a food-borne outbreak, with turkey salad as the vehicle, since stool cultures from 61 asymptomatic persons, who had eaten in the cafeteria on the suspect dates but who had not eaten the turkey salad, did not reveal Shigella organisms.

On the Control of Antibiotic Discs in Canada. L. Greenberg and K. M. Fitzpatrick. Canad. M. A. J. 79:383-386 (Sept. 1) 1958 [Toronto].

Improperly made and improperly labeled antibiotic disks present a serious health hazard in that a disk labeled to contain 10 units of antibiotic but, in fact, containing only 1 unit, if used in testing the sensitivity of an organism isolated from an infectious process in a patient, could give rise to misleading results which might deny the patient the use of a lifesaving drug. If the same disk labeled as containing 10 units actually contained 30 or more units, false-positive results would be forthcoming, and the patient would then be given a preparation that would have little or no therapeutic value. In a survey of antibiotic disks distributed in Canada, it was found that in many instances there was little correlation between the labeled claims and the assayed potency. The differences were extreme, with disks with no trace of antibiotic present and others with potencies varying from 1/10th to 3 or 4 times that declared on the label.

During the period under review, 640 lots of antibiotic disks, representing products from 4 manufacturers, were received and assayed at the Laboratory of Hygiene. A total of 1,186 individual components were assayed by the extraction technique, and, in addition, a number were subjected to performance tests. The results of assays of antibiotic sensitivity disks entering Canada between March, 1957, and June, 1958, revealed that in 3 companies more than 84% of the antibiotic disks received were acceptable; that in 2 companies more than 83% of the sulfonamides, etc., were acceptable; that in 2 companies 71 and 52% of the multiple antibiotic disks assayed were acceptable; and that in 1 company 75% of the individual components and 87% of the multiple sulfonamides were acceptable. Two companies showed marked improvement during the assay period, the rejection rate for company A dropping from 15% to zero and that for company C dropping from 75% in the first 6 months to 15% in the last 6 months. It is of note that most of the manufacturers rely almost exclusively on the use of performance tests for controlling their products, the result of which was a high proportion of faulty lots. For this same reason the authors developed the present assay method utilizing an extraction technique. The control program is to continue, and more effective regulations are being considered.

BOOK REVIEWS

Variables Related to Human Breast Cancer. By V. Elving Anderson, Harold O. Goodman, and Sheldon C. Reed. Study from Dight Institute of Human Genetics. Cloth. $4. Pp. 172, with 7 illustrations. University of Minnesota Press, Minneapolis 14, 1958.

This book presents a careful statistical analysis of the incidence of cancer of the breast in close female relatives of patients with this disease. The material studied is taken from the tumor clinic of the University of Minnesota Hospitals. The authors call attention to the fact that this source introduces ethnic, economic, and residential factors of selection. The corresponding relatives of husbands are used as controls. This has a tendency to minimize environmental differences. The follow-up is excellent. An effort is made to evaluate genetic factors, and the limitations of the method are described. The findings of prior studies that mothers, sisters, and daughters of breast cancer patients have a higher incidence of the disease than is found in the controls and in the general population is confirmed. To the extent possible, the results of this study are compared with those of other reported series. The pitfalls of statistical conclusions are delineated, and certain courses of future research are indicated. The paucity of clinical material limits the value of the book for those who are concerned only with clinical medicine. This is a careful and conservative presentation which should be valuable to those whose range of interest includes statistical studies and the epidemiology of cancer of the breast.

Orr's Operations of General Surgery. By George A. Higgins, M.D., F.A.C.S., Associate Professor of Surgery, University of Kansas School of Medicine, Kansas City, and Thomas G. Orr, Jr., M.D., F.A.C.S., Associate in Surgery, University of Kansas School of Medicine. Third edition. Cloth. $20. Pp. 1016, with 835 illustrations. W. B. Saunders Company, 218 W. Washington Square, Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1958.

This edition was begun by Orr, the original author, but the task was interrupted by his sudden death and the two present authors completed the task. The book must be objectively evaluated on the basis of a work purportedly to be of value at this time. The volume is well bound and profusely illustrated, and the type is large and easily read. It is, however, difficult to recommend it as a textbook on operative surgery. A number of rather curious features are presented. For example, on page 38 there is a description entitled "Technique of Fillet of Finger," an operation in which the normal skeletal structures of the fifth digit are electively excised to afford a soft tissue tube that can be opened and used as a flat flap to cover a defect on the lateral aspect of the hand, but several pages later flap formations from the chest or abdominal walls to accomplish the same purpose without elective sacrifice of a digit are described. No discussion of the advantages or disadvantages of either method is presented. A technique of lower extremity amputation by transection through the neck of the femur and ascribed to G. M. Huggins with a 1918 reference appears in the chapters on amputations. A rather involved description of orderly surgical tracheostomy is given, in contrast to emergency tracheostomy with no discussion of the relationships of the former to other major procedures in the neck and no correlation with radical cervical lymphadenectomy.

On page 248, the technique of closed thoracostomy is described in which it is recommended that the preferable site of introduction of the catheter is in the second or third intercostal space in the midclavicular line. For simple mastectomy, elliptical incisions with removal of much skin is depicted—a procedure described as closely approaching radical mastectomy—while no mention is made of the transverse incision and preservation of skin for cosmetic purposes. In the discussions of extended radical mastectomy, the internal mammary nodes are considered but no mention is made of possible concomitant supraclavicular node dissection. The descriptions for operations on the alimentary tract include nothing that could not have been just as well stated years ago. One comment is unavoidable in this connection, and that applies to what is said about the technique of appendicial abscess drainage: "If the abscess lies away from the abdominal wall, the free peritoneal cavity may be opened. A gauze pack placed down to the abscess, to be removed in five or six days, will form a channel for exit of pus without contaminating the peritoneum." A cardinal principle in the drainage of periappendical abscesses is their immediate evacuation via a route that avoids peritoneal cavity exposure from the outset. The chapters on the somatic and sympathetic nervous systems are concise and well written from the standpoint of a general surgeon who may be called on to perform certain procedures when a neurosurgeon is not available. In the chapter on the endocrine system, a subject rather superficially dealt with, not enough attention is devoted to the anterior transperitoneal approach to the adrenals. The operations on the

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

genitourinary system are incompletely and very sketchily dealt with, and the same may be said for the chapter on gynecology. The operation for construction of an ileal bladder is described in detail, yet nothing is said about pelvic exenteration, a part for which the ileal bladder procedure was originally revived in its modern form. While the book contains many good illustrations, most of these are not original but are redrawn or reproduced from other works. After chapters dealing with various categories of regional surgery, there are brief bibliographies, but these are far from comprehensive and the most important references are not necessarily cited.

Roentgenology of the Chest. Edited by Coleman B. Rabin, M.D., F.C.C.P., Assistant Clinical Professor of Medicine, College of Physicians and Surgeons, Columbia University, New York. Editorial Committee: Benjamin M. Gasul and others. Sponsored by American College of Chest Physicians. Cloth. $19.50. Pp. 484, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

This book represents a bilateral approach to the subject of diseases of the chest, intertwining the clinical aspects with the roentgenographic findings. The objective of the authors is to present roentgenology of the chest to the roentgenologist from the clinical standpoint and to the clinician from the radiologic point of view. This has been accomplished admirably. To effect this objective 50 experts (roentgenologists and clinicians) have contributed 39 chapters. Each chapter presents a masterful exposition of a particular phase of the general subject. The book covers diseases and abnormalities of the thoracic wall and its contents, including circulatory disturbances, heart and great vessels, pulmonary circulation, and the diaphragm. Greatly enhancing the value of the presentation are chapters devoted to such subjects as the possibilities and limitations of x-ray diagnosis, normal roentgenographic appearances, mass fluorography, methods of x-ray examination, and special signs in chest roentgenography. To detect and identify the abnormal, a thorough knowledge of the normal is essential. The subject matter is beautifully illustrated with excellent reproductions of roentgenograms. A bibliography is at the end of each chapter, in some instances not too extensive but adequate, and an excellent subject index and index of authors is provided. The contributors have presented the subject matter in a clear, concise, but comprehensive manner. The editor, editorial committee, contributors, and the publishers deserve commendation for producing such a comprehensive and excellent compilation. This book is highly recommended to any physician interested in chest disease. Certainly roentgenologists, chest physicians, and thoracic surgeons should not fail to add it to their library.

A Synopsis of Surgical Anatomy. By Alexander Lee McGregor, M.Ch., F.R.C.S. With foreword by Sir Harold J. Stiles, K.B.E., F.R.C.S. Eighth edition. Cloth. $7. Pp. 808, with 766 illustrations by Dr. E. A. Thomas. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; John Wright & Sons, Ltd., 42-44, Triangle West, Bristol 8, England, 1957.

This reference book, which first appeared in 1932, is now in its eighth edition. Such a reception is a commendation in itself. With each edition refinements and new material have been added. This one contains new sections dealing with adrenalectomy, injuries to the large lymph ducts, and paragangliomas. A feature of particular value to the busy surgeon is the manner of presentation of anatomic facts. The contents of the book are presented as separate essays, any one of which is complete in itself. This book is not meant as a classical textbook of anatomy. The author has focussed his attention on anatomic facts, of practical value, to the student and the physician in practice. He has achieved his purpose by correlation and contrast of the pertinent facts. The discussion of the lymphatic system and its role is praiseworthy. With the necessity of removal of lymph nodes, when performing operations for cancer, the value of such a well-documented analysis of this system becomes more evident. The illustrations and the carefully worded legends are well placed, lucid, succinct, and accurate. The format is attractive. The author has a charming manner of expression which adds to the pleasure of reading. This book, which has been a hallmark of anatomy textbooks for the surgeon for many years, excels the previous editions. It is a welcome addition to the list of necessary books for the student, the surgeon, and all teachers of surgery.

Cardiovascular Diseases. By David Scherf, M.D., F.A.C.P., Professor of Clinical Medicine, New York Medical College, Flower and Fifth Avenue Hospitals, New York, and Linn J. Boyd, M.D., F.A.C.P., Professor and Director of Medicine, New York Medical College, Flower and Fifth Avenue Hospitals. Third edition. Cloth. $17.75, Pp. 829, and 119 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W. C. 1, England, 1958.

Almost 10 years have elapsed since the previous American and British editions of this book were published, although several editions have appeared in a number of foreign languages. This third English-language edition is completely revised, and many new sections have been added. An excellent bibliography follows each chapter and suggests pertinent references and appropriate articles up to March, 1957. The entire field of cardiovascular diseases is covered, and special emphasis is given to the clinical manifestations of disease. The history and physical examination, rather than instrumental and laboratory methods, are stressed, and signs and symptoms are discussed from anatomic, physiological, and pathological viewpoints. The book is filled with pertinent observations and findings which have been gathered through years of wide experience by competent teachers. Therapeutic procedures for special conditions are discussed in a realistic manner throughout the book, but the last chapter deals more completely with agents that are helpful in the management of cardiac failure. Electrocardiography is discussed only briefly, because the authors have published a companion book on clinical electrocardiography. This excellent book should be useful to all students of medicine regardless of their training.

Functional Bracing of the Upper Extremities. Written and illustrated by Miles H. Anderson, Ed.D., Director, Prosthetics Education Project, School of Medicine, University of California, Los Angeles. Edited by Raymond E. Sollars, Associate Director, Prosthetics Education Project. Cloth. $9.50. Pp. 463, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

This is the first book on techniques of making and fitting functional braces for patients with paralytic disabilities of the upper extremities. The braces utilize power or force from springs, rubber bands, or functioning muscles to provide basic movements lost by paralytic disorders. This extensive work is devoted primarily to concise descriptions, with profuse use of photographs of the step-by-step fabrication of functional supports and devices that have proved reasonably successful. The author has indicated the basic devices available commercially to kit form. There are chapters devoted to the functional anatomy of the hand, upper extremities, and shoulder girdle, as well as chapters on the principles of biomechanics of functional bracing. Functional bracing is a relatively new concept to many physicians, as well as orthotists, and this book is an excellent "first" in the field. It should be a useful reference to physicians, particularly physiatrists, orthopedists, and neurologists, who are concerned with poliomyelitis and other paralytic conditions involving the upper extremities. Orthotists and others who make the devices should find this book a valuable part of their library. Occupational and physical therapists should have ready access to this volume.

Theory of Psychoanalytic Technique. By Karl Menninger, M.D. Menninger Clinic monograph series no. 12. Cloth $4.75. Pp. 206, with 15 illustrations. Basic Books, Inc., 59 Fourth Ave., New York 3, 1958.

The author is one of the foremost psychoanalysts in the United States and one of the first trained here, but he has never ceased to be a physician, psychiatrist, and teacher. In fact, his extensive creativity has expressed itself in countless ways, including developing a gigantic training center at Topeka, Kansas. He is, therefore, well qualified for the authorship of an authentic book on psychoanalytic technique, which he presents in an undogmatic, easily understood way with illustrations and cogent extractions from the literature. An instructive bibliography and an adequate index are included. The book is highly recommended not alone for student analysts but for all psychiatrists interested in psychodynamic psychotherapy.

Atrial Arrhythmias, Digitalis and Potassium. By Bernard Lown, M.D., Research Associate in Medicine, Department of Nutrition, Harvard School of Public Health, Boston, and Harold D. Levine, M.D., Assistant Clinical Professor of Medicine, Harvard Medical School, Boston. Cloth. $6.90. Pp. 222, with 53 illustrations. Landsberger Medical Books, Inc., 51 E. 42nd St., New York, 1958.

This monograph is concerned with the analysis of 64 cases of paroxysmal atrial tachycardia with atrioventricular block caused by digitalis intoxication. The authors point out that this manifestation of digitalis toxicity has been increasing in incidence in the past few years as patients with congestive heart failure are treated vigorously with such drugs as mercurial diuretics which may cause cellular potassium depletion. Treatment for this condition is to stop digitalis and diuretic administration temporarily and give the patient potassium. The use of a chelating agent, such as sodium ethylenediaminetetraacetate, to induce hypocalcemia is also advocated in certain cases. The relationship of the potassium and calcium ions to digitalis dosage and toxicity is discussed at some length, as well as the clinical and electrocardiographic differentiation from other arrhythmias. The book is well illustrated, and the text is well written and easy to read. It is recommended for internists and cardiologists.

Hospital Planning for the Anesthesiologist. By William H. L. Dornette, M.D., Professor of Anesthesiology and Head of Department, University of Tennessee College of Medicine, Memphis. Publication number 335, American Lecture Series, monograph in American Lectures in Anesthesiology. Edited by John Adriani, M.D., Director, Department of Anesthesia, Charity Hospital, New Orleans. Cloth. $5.25. Pp. 119, with 31 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W. Toronto 2B, Canada, 1958.

Most anesthesiologists spend their full time in hospitals. More than other physicians, with the possible exception of radiologists, they are concerned with construction and planning problems. Starting with the operating room, recovery room, intensive therapy unit, oxygen distribution systems, communications, elevators, equipment storage, and air conditioning, it is reasonable that their interest might spread to include the entire hospital. This has been the author's experience. In one small volume, he has assembled many interesting suggestions for the more efficient development of a hospital, including such broad aspects as the selection of an architect, the proper site for the building, and a more detailed analysis of key areas within.

The volume is another in the American Lecture Series and should be of value to hospital administrators, members of medical boards, engineers, physicians who are departmental chiefs, head nurses, and those in position to influence the alteration of existing structures or the planning of new ones.

Human Dissection: Its Drama and Struggle. By A. M. Lassek, M.D., Ph.D. Cloth. $6.50. Pp. 310, with 16 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

Before any authentic teaching of anatomy was possible it was necessary to dissect human bodies. Where the means of preserving them were not available, this had to be accomplished quickly in prolonged sessions so that the job could be completed before decomposition made it impossible to determine the relationships of the soft parts. The procurement of a sufficient number of bodies has always been and still is a major problem. These problems are treated from the historical viewpoint, and a detailed and interesting account of the activities of the grave robbers of bygone times is presented. Although the time devoted to anatomy in the curriculums of medical schools has decreased in recent decades, the author warns that unless this trend is reversed the quality of medical education must suffer. There is a bibliography and an index. This book should be of interest to students of medical history, anatomists, and medical educators.

A Doctor Speaks His Mind. By Roger I. Lee, M.D. Cloth. $3. Pp. 120, with 1 illustration. Little, Brown & Company, 34 Beacon St., Boston 6; Little, Brown & Company (Canada) Ltd., 25 Hollinger Rd., Toronto, Canada, 1958.

This little volume is a collection of short articles giving the author's opinion on many subjects. Dr. Lee's opinions will be respected by all members of the medical profession and should find agreement in the minds of most. He takes a dim view of governmental interference in the practice of medicine and warns that there are many things that may be pointing the way to control of the profession by the government. He writes on such subjects as "Are There Enough Doctors?" "Is Blue Cross–Blue Shield a Menace?" "Crusades," and "Hero Worship." Throughout all of these essays is woven the common sense of one of America's outstanding and beloved physicians. It is well worth reading.

Basic Clinical Parasitology. By David L. Belding, M.D. Cloth. $9. Pp. 469, with 118 illustrations. Appleton-Century-Crofts, Inc., 35 W. 32nd St., New York 1, 1958.

Although this book, written primarily for medical students and physicians, is not meant to take the place of the author's more comprehensive "Textbook of Clinical Parasitology," it covers the subject very well. After an introductory chapter, sections are devoted to the protozoa, roundworms, tapeworms, flukes, and arthropods. A final section deals with technical methods for the diagnosis and treatment of parasitic diseases. Many helpful charts and tables are included and the diagrams and other illustrations are excellent, except for their lack of color. This is especially regrettable in the pictures of plasmodia. In the last section, insect repellents are discussed, but there is no mention of attractants. Aside from these two minor criticisms the book is excellent and should find a ready place in teaching and practice. Pertinent references to current literature are given, and both a subject index and an author index are provided.

Epilepsy Handbook. By Frederic A. Gibbs, M.D., Professor of Neurology and Director of Division of Electroencephalography, University of Illinois, School of Medicine, Chicago, and Frederick W. Stamps, M.D., Director of Consultation Clinic for Epilepsy, University of Illinois, School of Medicine. Cloth. $4.75. Pp. 101, with 8 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

This handbook is exactly what the authors intended it to be: a compact, practical compendium of useful knowledge about epilepsy. In 1952, Dr. and Mrs. Gibbs published a bulky "Atlas of Electroencephalography," which included detailed data about more than 10,000 of their epileptic patients. The present handbook is a distillation of the experience of the authors. Especially useful are the 30 pages about therapy, supplemented by three summarizing tables and a two-page colored reproduction of various antiepileptic drugs. The authors give a straightforward, succinct account of epilepsy and its treatment. The book is an authoritative, handy reference for anyone who has anything to do with epileptic patients.

Medicine and Man: The Story of the Art and Science of Healing. By Ritchie Calder. Mentor book MD 217. Paper. 50 cents. Pp. 256. New American Library of World Literature, Inc., 501 Madison Ave., New York 22; cloth bound book published by George Allen & Unwin, Ltd., 40 Museum St., London, W. C. 1, England, 1958.

This paper-bound book should be interesting to those of the public who follow medical history and progress, but it also offers enough information to be useful as a reference source for physicians. Medical histories may appeal more to the older part of the population, whether it be medical or otherwise, but this may be in part because of the lack of attention that has been directed to this aspect of medicine. If presented interestingly, there is no reason why history should not be well received because at times it provides a therapeutic index. In any event this little booklet provides interesting reading.

QUESTIONS AND ANSWERS

RADIOACTIVE IODINE TEST

To the Editor:—*What are the different factors that may influence the radioactive iodine uptake in a patient and how? How long after an intravenous pyelogram or a gallbladder series can the protein-bound iodine level be determined?*

Antonio D. Talusan, M.D., Baltimore, Md.

Answer.—Several medicaments and contrast mediums for diagnostic roentgenograms may influence the collection of radioiodine. Iodides, whether administered in the form of potassium iodide, cough medicines, asthma compounds, or vitamin tablets, usually inhibit the collection of radioiodine by the thyroid gland for as many as 10 days after use of the medicament has been stopped. Antithyroid drugs, such as propylthiouracil or methimazole, can be expected to block the collection of radioiodine by the thyroid gland during the period of administration of the drug, but, within two or three days after use of the medicament has ceased, the uptake of radioiodine may be markedly elevated for some weeks. The making of an intravenous pyelogram usually blocks the uptake of radioiodine in the euthyroid patient for 5 to 10 days, and the making of a roentgenogram of the gallbladder will block the uptake of radioiodine in the same person for some months, perhaps three to six. On the contrary, in some patients with exophthalmic goiter, the uptake of radioiodine by the thyroid gland may be abnormally high immediately after intravenous pyelograms or cholecystograms are made; the reason for this is not known. Pantopaque myelograms, or examination of the bronchial tree with the aid of iodized oil may interfere with the uptake of radioiodine for as long as the iodized oil can be seen in roentgenograms. The value for serum protein-bound iodine usually is abnormally high for a week to 10 days after an intravenous pyelogram has been made. After a roentgenogram of the gallbladder has been made, the value for serum protein-bound iodine will be completely out of range for a period varying from several months to several years after the dye has been employed, depending on the particular dye used.

DESENSITIZATION TO NICKEL

To the Editor:—*A patient has been proved to be nickel-sensitive by an intradermal test (with a specially prepared solution of nickel and suitable control injection). Would it be in order to employ a method of gradually increasing amounts of specially prepared nickel solution subcutaneously—similar to the method of desensitization against other known allergens? If this is done, would there be a gradual build-up of antibodies? If not, how would desensitization be achieved? Above all, would such repeated injection of a metal be hazardous, inasmuch as it may lead to sarcoma, or may one safely proceed with such therapy?*

David N. Shapiro, M.D.
Johannesburg, South Africa.

Answer.—Sensitivity to nickel should be determined only by patch-testing with a 10% aqueous nickel sulfate solution, usually on the arm or back. The patches should remain for two days unless there is pronounced irritation. As a general rule, one cannot be desensitized against chemicals. However, Urbach and Gottlieb (Allergy, New York, Grune & Stratton, Inc., 1943, p. 264) reported on two female patients who had widespread dermatitis for months and showed a definite eczematous reaction to patch tests with even a 1:1,000,000 solution of nickel sulfate. Successful desensitization was achieved by a gradual increase in concentration of subcutaneous injections of nickel sulfate administered twice daily until a strength was reached that produced strong local and focal reactions. Attempts at desensitization to nickel by patch-testing and by ionization proved unsuccessful. Spontaneous hyposensitization to nickel may occur within months to two years if the reaction to patch test is 2+. The chances are slim, and it may take years if the reaction is 4+ (Rubin, Department of Allergy, Skin and Cancer Unit, New York, personal communication). In a series of 54 patients known to have been sensitive to nickel, who were examined after an interval of 1½ to 11 years, 31 (57%) demonstrated a persisting sensitivity and 23 gave negative results to patch tests. Eighteen of these patients continued to have eczema, although they were no longer sensitive to nickel (Morgan, *Brit. J. Dermat.* 65:84, 1953). With regard to possible malignant (sarcomatous) changes caused by subcutaneous injections of nickel sulfate solution, there is a report that nine fatal cases of cancer of the inside of the nose over a period of 11 years occurred in a nickel refining plant

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

(White, Dermatergoses; or Occupational Affections of the Skin, London, H. K. Lewis & Co., 1934, p. 161). Both nickel and arsenic were under suspicion in the high incidence of cancer in the lung and in the nasal sinuses, especially in the ethmoid, in workers exposed to nickel. It is most likely that arsenic, the impurity in nickel ores and in the sulfuric acid used to extract the copper from nickel ores (Donald Hunter, Diseases of Occupations, London, English Universities Press, 1957, p. 442), and nickel carbonyl (Hueper, Occupational Tumors and Allied Diseases, Springfield, Ill., Charles C Thomas, Publisher, 1942, p. 418), a highly toxic gas, were responsible for the high incidence of cancer in those workers. It is of interest to note that no tumors developed in mice, so susceptible to anticancer agents, when given nickel intravenously, intraperitoneally, or intramuscularly (Hueper, *J. Nat. Cancer Inst.* 16:55, 1955).

PRIMARY FAILURE OF ANTERIOR PITUITARY

To the Editor:—*A 26-year-old woman had her first menses at the age of 11 years; this was so profuse that she went into shock. Laparotomy was done, and a bicornate uterus was repaired. The ovaries were normal. In the ensuing 15 years she had completely irregular menses, and five or six times dilatation and curettage was performed for severe prolonged bleeding. Endometrial hyperplasia was reported. She has been married two years without becoming pregnant. Recent studies have shown bleeding and clotting times, platelet count, and prothrombin time to be normal; basal metabolic rate, 23%; radioactive iodine uptake, 43%; protein-bound iodine level, 6.1 mg.%; follicle-stimulating hormone level, less than 4.3 mouse units in 24 hours; cholesterol level, 195 mg.%; albumin level, 4.7 Gm.%; and globulin level, 3.1 Gm.%. Physical examination showed normal female characteristics, including a normal pelvis. A diagnosis of primary failure of the anterior pituitary was established, and cobalt radiation of the pituitary and ovaries with 100 r per month for six months was recommended. Is this diagnosis tenable? Is there any evidence to show that cobalt radiation will be of any help to this patient? What is the danger of using this amount of cobalt radiation?*

T. F. Reszel, M.D., Bayonne, N. J.

Answer.—The diagnosis of primary failure of the anterior pituitary has not been fully documented. The follicle-stimulating hormone level is low, but determination must be repeated for confirmation. Further, it would be quite unusual to have bleeding with endometrial hyperplasia in the presence of primary failure of the anterior pituitary gland. Ovarian pathology cannot be ruled out, despite a normal pelvic examination. Culdoscopy or pneumoperitoneum may be helpful in establishing the possibility of ovarian pathology. Cobalt radiation may be beneficial to this patient, but there are dangers in its use. Even though the dosage is rather small, the recommendation of treatment over a period of six months may induce ovulation and pregnancy with a possibility of damage to a very early embryo. Therefore, the possibility of pregnancy occurring during the time of radiation must be prevented. Further, there is danger of inducing genetic mutations with the possibility of abnormalities occurring in future generations. It would be very wise to explain these dangers to the patient before cobalt or x-ray irradiation is used. This consultant would certainly advise exploration of other methods of treatment before resorting to irradiation.

AMBLYOPIA EX ANOPSIA

To the Editor:—*A boy, now 13 years of age, was discovered to have defective vision in the right eye at the age of 10. No strabismus or other external defect is present. Vision in the affected eye is 20/50 and in the other eye 20/15. Competent ophthalmologists advised, even when the defect was first discovered, that glasses would be of no value in correction. There has been a slight increase in the visual defect in the weak eye in the past 12 months, but it is still advised that glasses would not help and that they may even cause harm. The diagnosis is amblyopia ex anopsia. Loss of vision is from lack of use of the eye. May further increase in visual defect be expected in the weak eye? Will proper glasses do anything to check the loss or even improve the vision? Is there a danger of this eyeball becoming smaller or of a squint developing?*

H. D. McCormick, M.D., Vincennes, Ind.

Answer.—One should have more information regarding the boy referred to in this question to properly discuss his needs. Details of ophthalmoscopic examination, refraction with and without cycloplegia, and ocular motility and some information of the boy's general physical and mental condition should be given. The diagnosis of amblyopia ex anopsia may be nothing more than a description of symptoms. It does not rule out hereditary disease or acquired disease of the sensory elements of the eye. The low visual acuity in the right eye was discovered at the age of 10, but the amount of his visual acuity at that time is not given. Three years later the vision in the affected eye is 20/50, but there is no statement as to whether this is with or without glasses. There is a bit of ambiguity in the statement "there has been a slight increase in the visual defect in the weak eye in the past 12 months." Does that mean that the visual acuity is less or greater than it was 12 months ago? The statement that "loss of vision is from lack of use of the eye" is not supported by any form of proof or information from which such a deduction can be made. Whether further increase in the visual defect is to be expected depends entirely on what is meant by visual defect. One does not speak of loss of vision as an increase in visual defect with clear understanding. Glasses are prescribed for one purpose only, and that is to improve visual acuity. There is no therapeutic value in the wearing of glasses. If the visual acuity of the right eye is better with glasses than without, then there is a good possibility that a child's vision could be improved by training with glasses and orthoptic exercises.

ELECTROMYOGRAPHY

To the Editor:—*Please evaluate electromyography in diagnosis and appraisal of muscular degeneration as related to neurological and/or muscular cause.*

Maurice J. Regan, M.D., Wilkes-Barre, Pa.

Answer.—Electromyography is being recognized by an increasing number of physicians as a valuable aid in the diagnosis of neuromuscular disease. Its most frequent use is in the diagnosis of conditions affecting the lower motor neuron, based on its ability to detect even minimal denervation of muscle. At times, when clinical tests fail to indicate clearly whether muscle dysfunction is attributable solely to pain, hysteria, malingering, disuse, upper motor neuron lesions, and the like, or whether it is the result of disease affecting the lower motor neuron, electromyography may present the only readily available objective evidence of disease of the lower motor neuron. It aids in the location of lesions affecting the lower motor neuron in the diagnosis of root, plexus, and peripheral nerve lesions, because the distribution of affected muscles can be determined more discreetly than by other methods. It is useful in detecting minimal residual innervation and in detecting reinnervation weeks before other evidence of it can be had. Characteristic patterns also result from primary disease of muscle fibers. Especially when combined with tests of the speed of conduction in nerves, electromyography is a genuine aid in the separation of myopathies from neuropathies and in separation of peripheral neuropathies from diseases affecting primarily the motor cells in the spinal cord. Electromyography offers a variety of clues to the nature of the muscle dysfunction, and, when combined with the neurological examination and other procedures, it will significantly improve the accuracy of diagnosis of diseases affecting the motor unit. Successful use of electromyography requires experience in eliciting and interpreting the electromyographic patterns of neuromuscular disease and familiarity with the neurological problems involved. One should not underestimate either the usefulness of the technique or the skill and knowledge required to use it to advantage.

FUNCTIONAL LARYNGITIS

To the Editor:—*A woman, aged 55, says she "can't talk very good." Her voice box tightens when she begins to talk, and it is a strain for her to talk. The weather has no effect on this trouble, and she has had no throat surgery of any type. The onset was 12 years ago, when she had something "break" in her throat. Before that time, she had no trouble talking. Examination with a laryngeal mirror showed her true cords to be white and smooth and to move readily with phonation and respiration. On phonation, she was able to hold the cords in approximation and there was no bowing. The remainder of her ear, nose, and throat examination revealed entirely negative results. Her blood pressure is slightly elevated (188/100 mm. Hg). Her history, with the exception of a streptococcic sore throat in 1957 and a premature menopause 12 years ago, secondary to surgery, is completely negative. The onset appeared before her premature menopause. Please give suggestions and ideas concerning the patient's complaint.*

M.D., Ohio.

Answer.—The normal approximation of the vocal cords on phonation and the absence of any visible pathology in the larynx after 12 years of vocal difficulty lend support to the presumption that the patient's symptoms are on a functional basis. Direct laryngoscopy would be of supplementary aid in ruling out organic disease and would have the additional advantage, through premedication and local anesthesia, of inducing sufficient muscular relaxation to produce a temporarily normal voice. It is entirely possible that an attack of acute laryngitis was responsible for the patient's initial episode of hoarseness and that the dysphonia has continued as a nervous phenomenon. Appraisal and voice training by a competent speech therapist should be recommended. The inquirer will find much of interest in a book entitled "The Voice of Neurosis" by Moses (New York, Grune & Stratton, Inc., 1954).

FAILURE OF INTRAVENOUS INFUSIONS

To the Editor:—*Many intravenous feedings and transfusions started in hospitals cannot be completed and must be restarted. What are the percentage and the causes of such failures? Are they all due to dislodgment of the needle in the vein, or are other factors involved?*

M.D., Pennsylvania.

Answer.—A survey was made on seven surgical wards, totaling about 200 beds, and it was found that about 450 intravenous infusions of fluid and 27 blood transfusions are given on these wards per month. This does not include those given in the operating room. Of these, 185 are started by a doctor, 250 by a nurse anesthetist, and 15 by a ward nurse. There are about 55 failures or restarts each month, an incidence of 12.2%. A number of factors are involved in failures necessitating a restart: (1) poor or inaccessible veins due to infancy, obesity, or such factors; (2) poor placement of the needle and poor choice of site, allowing easy dislodgment; (3) improper insertion of the needle, with puncture of the posterior wall, or poor anchorage, allowing dislodgment; (4) extreme restlessness of the patient; and (5) moving and transporting the patient from operating table to litter to bed in the recovery unit to litter to ward bed. There were no reactions to intravenous infusion in the period of study, so this was not a factor in failure to complete the infusion. There was a 1% incidence of minor reaction to blood transfusion, but this often is not immediate and does not necessarily terminate the transfusion prematurely. It is apparent that most failures and restarts are due to human error factors. Insertion of a plastic catheter through the needle for retention in the vein obviates some but not all of the failures. However, this consultant's experience is that thrombophlebitis eventuates in about 48 hours. Rate of flow of intravenous infusion was not incriminated but is important. Too rapid flow may cause leaking around the needle, with external compression of the vein and failure. Too slow a flow fatigues the patient to the point that he moves or may intentionally remove the needle.

LABORATORY TESTS WITH STORED SERUM

To the Editor:—*Is there published evidence showing the degree of "change" which occurs in cephalin flocculation, thymol turbidity, and the bilirubin level when serum is stored (refrigerated but not frozen) for more than 24, 48, or 72 hours? It is stated in certain textbooks that the cephalin flocculation becomes "more positive" and the bilirubin level "decreases" when such a delay occurs and, hence, results are not valid. Has this been proved, and has the degree of alteration been demonstrated by any actual quantitative study?*

M.D., California.

Answer.—The bilirubin content of serum remains unchanged for days when kept cold and in the dark (Vahlquist, *Acta Pædiat.* [supp. 5] 28:1, 1941; With, *Nord. med.* 13:721, 1942). However, serum bilirubin, especially the direct-reacting fraction, is sensitive to oxidation and sunlight (Coolidge, *J. Biol. Chem.* 132:119, 1940). There is no significant change in thymol turbidity values after storage of serum in a refrigerator for 17 to 24 hours and, in some instances, for as long as seven days (Brieger and Friedman, *Occup. Med.* 2:463, 1946). To the knowledge of this consultant, there is no published evidence showing the degree of "change" which occurs in the results of the cephalin flocculation test when serum is stored in a refrigerator. Hanger (*J. Clin. Invest.* 18:261, 1939) originally stated, "The serum should preferably be fresh and preserved at icebox temperature." According to Pohle and Stewart (*J. Clin. Invest.* 20:241, 1941), blood should be drawn six hours prior to the performance of the test. Finally, Yardumian and Weisband (*Am. J. Clin. Path.* 13:383, 1943) reported that serum which has been refrigerated for one day or longer may yield false-positive results on testing.

AEROPHAGIA

To the Editor:—*A 61-year-old woman has had a complaint of belching for three months. Dietary measures have been used, such as giving smooth diets and getting the patient to eat slowly and not to swallow any excessive air. However, nothing seems to have eased the belching. As a matter of fact, the patient states that the condition is progressing. Please give an opinion as to the possible cause and advice as to future treatment.*

Jacob J. Altholtz, M.D., Brooklyn, N.Y.

Answer.—This history is that of a typical case of aerophagia. It is, however, important to be sure about any disturbed functions of the digestive tract. One should be particularly certain about any cardiac lesion, such as an esophageal hiatus hernia. Is the patient obese? If no organic or disturbed functions of the gastrointestinal tract are found, the patient should be advised to eat foods unlikely to form gas, to chew always with her mouth closed, and to open her mouth when she belches so that she may not reswallow the air. Make sure that she has regular and adequate bowel function, and, finally, instruct her to take small doses of charcoal powder, placing one-half teaspoonful of charcoal powder on the back of her tongue and washing it down quickly with a little water, about 10 minutes before each meal.

RADIOACTIVE IODINE TEST AND STEROIDS

To the Editor:—*What is the effect of corticosteroid therapy on the uptake of radioactive iodine? If there is any effect, how is it explained physiologically?*

Norman A. Schwartz, M.D., McKeesport, Pa.

Answer.—Moderate to large doses of corticosteroids administered over a period of several weeks suppress the pituitary production of thyrotropin, thereby producing a relative hypofunction of the thyroid gland. The radioactive iodine uptake in such instances will be in the low normal or hypothyroid range, and exogenous thyroid therapy is usually indicated.

INCREASE REPORTED IN INFANT DEATH RATE

Children's Bureau reports that for the first time in 22 years the rate of infant deaths is on the increase. The information was disclosed by Under Secretary Bertha S. Adkins of the Department of Health, Education, and Welfare at a convocation of the Children's Aid and Adoption Society of Orange, N. J.

Miss Adkins said that preliminary estimates for 1957 show an increase in the infant mortality rate from 26 per 1,000 live births in 1956 to 26.3. Infant deaths within the first month also increased slightly, from 18.9 per 1,000 in 1956 to 19 in 1957 and to 19.5 for the first eight months of 1958.

"This break in our progress in conserving infant life," she said, "means an estimated loss of more than 4,000 babies in 1957 and the first eight months of this year." The reverse has set in despite a doubling since 1945 of the percentage of infants who are served by well-child conferences.

Commented Miss Adkins: "Because of the large number of families that seek such services for their babies, it sometimes has been necessary to sacrifice quality of care somewhat. Many health departments are distressed that overcrowding of clinics makes it impossible for physicians to give adequate time and attention to the mothers and children who need medical guidance and care.

"These service problems are now generally more acute in the cities, because of the changing nature of city populations. In recognition of this, our social security law was amended at the last Congressional session to make grants-in-aid funds more generally available to city children. Previously, these grants had been predominantly available only to children in rural areas.

"Another development—the earlier discharge of mothers and infants from large municipal hospitals—emphasizes the need for more comprehensive supplementary community services, including services to mothers and their infants in their own homes."

MEDICARE COSTS AT RATE OF $9,200,000 A MONTH

In October, first month for cutback in the Medicare program, its costs rose to $9,200,000, highest since the operation began almost two years ago.

This fact was disclosed to the convention of the Association of Military Surgeons by Brig. Gen. Floyd L. Wergeland, who is in charge of the program. As for the future, General Wergeland says, "The ceiling is still unknown."

With costs mounting, the problem facing Gen. Wergeland is to somehow keep within the 72 million dollars Congress appropriated for the fiscal year ending next July 1. He is under instructions not to exceed this figure. If spending for the remaining months of the fiscal year continues at the October rate, the total will amount to about 106 million dollars, or more than 30 million dollars more than Congress authorized.

Commenting on restrictions that went into effect Oct. 1, General Wergeland said: "Obviously it will take some time before the kinks are ironed out of the revised procedures and programs. We hope that what we have done will achieve the ends we had in mind, but we do not know how it will work out in practice. Only time will tell."

If costs continue at a deficit pace, General Wergeland will have an opportunity to ask Congress for a deficiency appropriation when the new session opens in January.

NIH STUDYING IMPACT OF U. S. RESEARCH GRANTS ON 20 MEDICAL SCHOOLS

As a follow-up on the Bayne-Jones report, which recommends a tripling of medical research spending in 12 years, the National Institutes of Health is sounding out 20 representative medical schools to determine the impact on them of federal research grants.

To obtain the schools' reaction to the grants, as well as to the federal government's current policies and procedures in medical research, a team from NIH is touring the institutions and sitting down with officials in charge for round-table discussions.

Secretary Flemming of the Department of Health, Education, and Welfare disclosed the study in a talk to the Association of Land Grant Colleges. He said the medical school study was "just the beginning," that other similar investigations will be conducted by HEW and other federal agencies.

Mr. Flemming pointed out that these studies cannot yield the desired results unless the schools themselves make similar investigations. He added:

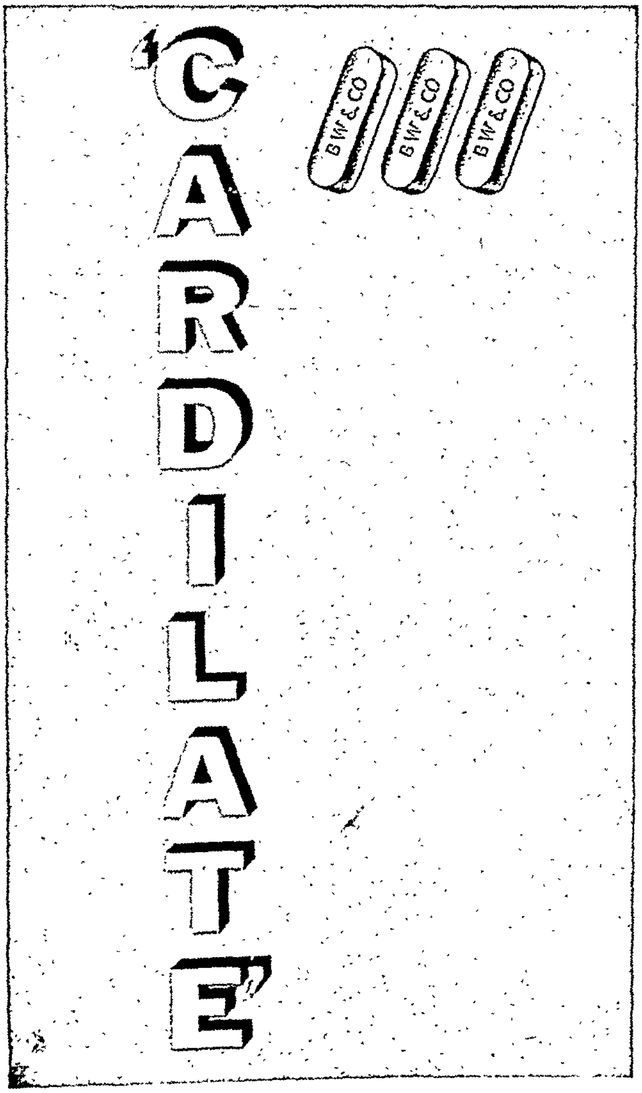
'CARDILATE' sublingual tablets for angina pectoris

"Nitroglycerin and erythrol tetranitrate when administered sublingually are among the most effective of all prophylactic agents available for the treatment of patients with angina pectoris. The comparatively prolonged duration of action of erythrol tetranitrate makes it especially valuable for clinical use."

Riseman, J. E. F., *et al.*: Circulation 17:22, 1958

'Cardilate' brand Erythrol Tetranitrate
Sublingual Tablets 15 mg., scored.

BURROUGHS WELLCOME & CO. (U.S.A.) INC.
Tuckahoe, N. Y.



"The federal government and our institutions of higher education have entered into a far-flung and tremendously significant partnership. I think it is significant that the President and Congress have said that the time has come to evaluate this partnership—not from the standpoint of its impact on the federal government but from the standpoint of its impact on institutions of higher education."

The secretary also warned of the dangers of too much federal interest in and possible control over education that might result from federal grants. He emphasized that states and local communities should not shirk their financial responsibility to education merely because U. S. money is available.

PRAISE FOR A. M. A. JOINT EFFORT AGAINST FOOD FADDISM

The joint educational program against food fac dism and quackery sponsored by the America Medical Association, National Better Business Bu reau, and Food and Drug Administration has bee highly praised by HEW Secretary Flemming. H told his press conference:

"In fighting quackery, law enforcement, of cours is only part of the answer. It is perhaps even mor important to help the public understand the fac about nutrition and to warn people against fals claims and theories."

FDA reports a disturbing increase in quacker involving false and misleading claims for a gre variety of vitamins, minerals, and other food su plements. "Unscrupulous operations in this fiel in fact, have become the most widespread and e pensive form of medical quackery in the countr today," Mr. Flemming said. He noted that th A. M. A. estimates that this racket is now costin 10 million Americans over 500 million dollars year.

The Secretary said FDA has 350 inspectors in th country and that this number is not enough. H declined to comment at this time on the FD budget now under consideration for submission t Congress in January.

DRIVE FOR AIR POLLUTION CONTROL ACT EXTENSION EXPECTED

Extension and possible expansion of the Air Po lution Control Act appears a *strong* possibility Senator Kuchel (R., Calif.), author of the law whic is now in its fourth year, promised the Nationa Air Pollution Conference he would work towar this end.

The act authorizes a total of 25 million dollar over a five-year period for research and investiga tion projects in causes and control measures for ai pollution. Congress has appropriated about 12 mil lion dollars so far. Commented Senator Kuchel "I regret that more funds have not been made avai able." In this connection, Surgeon General Burne of the Public Health Service told the conferenc that controlling air pollution "will cost big mone but it is an essential investment."

Dr. Burney and others saw a definite link be tween cancer and air pollution. He noted, for in stance, that cancer can be produced in animals b use of concentrates of urban smog. It is known tha lung cancer death rates in the largest cities ar twice as high as those in nonurban areas. The case has not yet been proved, but the weight of circumstantial evidence grows heavier as research progresses.

Dr. Chauncey Leake, assistant dean of Ohio State College of Medicine, cited two sources of pollution potentially dangerous. One comes from nuclear weapons testing "involving all living things now and to come." The other is exhaust fumes from automobiles.

Dr. Herman Hilleboe, commissioner of health for New York and former president of the American Public Health Association, advocated a crash recruitment and training program by PHS. It should be similar in scope to the crash programs in venereal disease and tuberculosis that were instituted in 1936 and 1944, Dr. Hilleboe said. Primary emphasis then was on loaning personnel to help states and communities set up effective disease control programs.

"A review of these contributions serves to underscore how much more can be done to achieve a major break-through in air pollution control. But to accomplish this the Public Health Service must first have the go-ahead signal from Congress," Dr. Hilleboe declared.

SHIPMENT OF ANTIBIOTICS TO IRON CURTAIN COUNTRIES PERMITTED

Shipment of antibiotics to Russia and satellite countries, long stringently controlled by the U. S. government, is now permitted under a Commerce Department decision. The policy does not apply to Communist China, North Korea, and North Vietnam, which are still out of bounds.

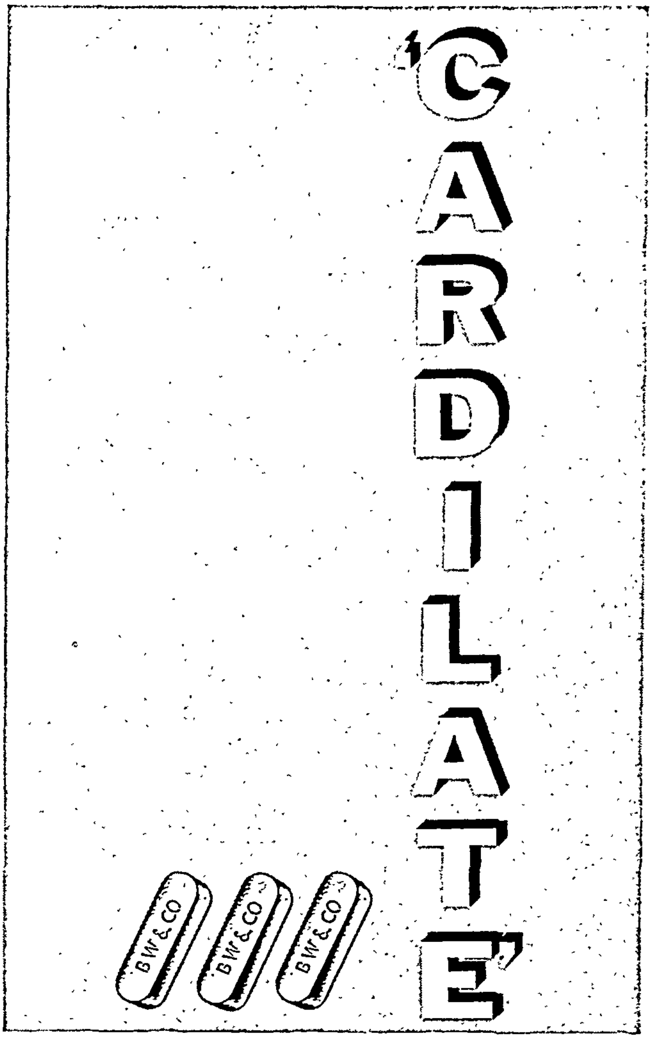
Relaxation of export controls will apply to such antibiotics as penicillin, streptomycin, aureomycin, terramycin, and similar drugs. Exporters still will have to apply for individual export licenses covering each shipment, with one exception. Shipments may be made to Poland under general export licenses.

MISCELLANY

Office of Civil and Defense Mobilization has set aside Dec. 7 as National Civil Defense Day with the slogan "Peace Through Preparedness." Plans call for exercises, rallies, exhibits, and nation-wide radio and television programs. "These activities are sponsored to impress upon every person in America that he must learn survival actions and incorporate civil defense preparedness into the pattern of his daily living," OCDM said.

The Dominican Republic has contributed another $100,000 to the special malaria fund of the Pan American Health Organization. This is the second installment of a $500,000 pledge made by the country last year for the fund, which has been set up to help finance the continent-wide eradication campaign. The U. S. has contributed $3,500,000, Venezuela $300,000, and Haiti $5,000. These are in addition to the annual quota assessments paid by member governments of PAHO.

A National Science Foundation survey indicates that three out of every four American scientists have some knowledge of at least one foreign language but only 2% have any knowledge of Russian.



'CARDILATE'
sublingual tablets for angina pectoris

Sublingual administration obviates inactivation of nitrites in gastrointestinal tract.

Most closely approximates nitroglycerin in frequency and degree of effectiveness.

'Cardilate' brand Erythrol Tetranitrate
Sublingual Tablets 15 mg., scored.

SAFETY OF LIQUID PLASMA—A STATISTICAL APPRAISAL

Wynn A. Sayman, M.D., Chicago, Ross L. Gauld, M.D., Washington, D. C., Shirley A. Star, Ph.D.
and
J. Garrott Allen, M.D., Chicago

Plasma was compared with whole blood with respect to the frequency of hepatitis after transfusion. The data represent more than 15 years of experience with a blood bank; the three categories of patients successfully followed up numbered 433 (plasma only), 1,242 (plasma plus blood), and 2,343 (blood only). Each plasma pool represented about 28 to 30 donors. After being tested for bacteriological contamination the plasma was stored in the fluid state for about six months in a room where the temperature ranged from 76 to 96 F (24.4 to 35.5 C) and averaged 89 F (31.6 C). The findings clearly showed that there is very little chance of serum hepatitis in a patient receiving pooled plasma stored for six months under these conditions, for there was not a single case of hepatitis among 305 patients who survived 180 days or longer after transfusions of plasma representing 12,345 donors. The incidence of hepatitis among patients who had received both plasma and whole blood was attributable solely to the whole blood. Plasma stored at lower temperatures than those recommended can transmit hepatitis despite a seven-month period of storage. Daily temperature records of the storage-space are therefore an essential feature of the procedure here advocated.

THIS REPORT summarizes the experience of the University of Chicago Blood Bank with respect to viral hepatitis among patients who received transfusions of plasma and/or whole blood. The patients studied were given transfusions during a period of slightly over 15 years, between September, 1942, and January, 1957, during which time the plasma administered was processed as described below. Of particular interest is the fact that no case of hepatitis occurred which could be ascribed to the use of plasma made in this manner. Follow-up data on the course of the recipients is complete for all but 2% of the patients who were given transfusions, and the results indicate that the risk of transmission of serum hepatitis from plasma can be reduced to less than that incurred with transfusions of whole blood.

Materials and Methods

Processing of Plasma.—The operation of the blood bank at the University of Chicago and its method of processing plasma has been described in detail in previous reports.[1] Briefly, all blood after being drawn from the donors was refrigerated until used for transfusions. If not used within five or six days, it was converted into plasma. Thus, the blood which was made into plasma was that which had become outdated before use. Beyond this, there was no selection. The plasma was first made up into preliminary pools from about 10 donors and placed in 2,000-ml. flasks. A final pooling was then made; this consisted of plasma which had been made from the blood of about 28 to 30 donors. It was then tested for bacterial contamination. Thereafter, it was

stored in the fluid state for periods of about six months in a room where the temperature ranged from 76 to 96 F (24.4 to 35.5 C) and averaged 89 F (31.6 C). (Demands created considerable variations in time and temperature, which will be reported later.)

Classification of Patients.—Recipients of transfusions were placed in three categories: (1) those who received plasma with no whole blood, (2) those who received both plasma and blood, and (3) those who received blood only.

Follow-up studies were attempted on all patients in groups 1 and 2 and on a 21% systematic random sample of group 3. The completeness of follow-up information for each group is indicated in table 1. In the majority of instances, the outcome was found in the records of either the blood bank or the hospital. An intensive effort was made to obtain follow-up data on patients whose final outcome was not previously known. The period of follow-up study comprised the six-month post-transfusion period, the generally accepted spread of the incubation period for serum hepatitis.

Table 1.—*Completeness of Follow-up Records in Three Groups of Patients Who Received Transfusions*

Follow-up and Survival Time After Transfusion	Group 1, Plasma Only (Sept., 1942-Jan., 1957)		Group 2, Plasma Plus Blood (July, 1946-Jan., 1957)		Group 3, Blood Only (21 % Random Sample) (July, 1946-Jan., 1957)	
	No.	%	No.	%	No.	%
Died in less than 30 days..	101	22.9	410	32.4	206	8.6
Died in 30-180 days........	27	6.1	179	14.2	243	10.2
Survived 180 days *or longer*..............	305	69.0	653	51.7	1,894	79.3
Not accounted for.........	9	2.0	21	1.7	45	1.9
Total	442	100.0	1,263	100.0	2,388	100.0
Total accounted for....	433	98.0	1,242	98.3	2,343	98.1

Due to the seriousness of the primary illnesses of patients who received transfusions, there was considerable mortality during the period of observation. Sixty-nine per cent of those who received plasma alone survived 180 days or longer; 52% of those who received both plasma and whole blood survived this period; and 79% of those given blood only lived 180 days or longer. In groups 1 and 2, the majority of deaths occurred before the seventh post-transfusion day, but in group 3 the majority of deaths did not occur until about the sixth week. The final analysis has therefore been confined to patients who developed homologous serum jaundice and to the survivors whose follow-up history covered at least 180 days after any episode of transfusion.

Group 1: In group 1 were 305 patients who received transfusions of plasma but no whole blood, who survived, and who were followed up for a full six months. An additional 128 patients died under known conditions but without jaundice before the 180th day; 9 patients could not be traced for the full 180-day period, but these, too, did not develop homologous serum jaundice. The initial number of patients comprising this group was 442. Thus, for this entire group, follow-up studies were successful in 98.0% of all patients who received transfusions.

Group 2: Group 2 included 653 patients who received transfusions of blood, together with plasma, and who survived for at least six months, except for three who died of homologous serum jaundice prior to this date. An additional 589 patients in this group died without jaundice or hepatitis prior to the 180th day; 21 patients could not be traced completely. The initial number of patients given transfusions in this group was 1,263, of which successful follow-up records were obtained for 98.3%.

Group 3: A total of 1,894 patients who received blood without plasma survived six months or longer; they were followed up for the full 180 days or until the occurrence of an episode of homologous serum jaundice. An additional 449 patients died prior to this time of known conditions without jaundice; and 45 patients could not be completely traced. The initial total of the patients in this group was 2,388, which comprised a 21% systematic random sample of 11,382 patients. Follow-up data were successfully obtained in 98.1% of all patients in this sample.

Diagnosis.—The diagnosis of serum hepatitis was clinical. A patient who developed clinical jaundice within 30 to 180 days after transfusion was considered to have serum hepatitis unless there was unequivocal evidence either clinically or pathologically that the jaundice was of different etiology. This criterion was applied consistently to all groups in the study, so that any anicteric cases of hepatitis which may have occurred were excluded from all three categories. As most patients were exposed to blood or plasma from more than one donor during the course of their hospital stay on any single admission, it was necessary to take into account the number of donors to which each patient was exposed and the duration of follow-up after each transfusion in arriving at our final conclusions. A few patients had more than one admission during which they received transfusions. However, each patient was counted only once, and if he developed homologous serum jaundice in the course of any admission he was always classified as having developed the disease.

Findings

The results of this follow-up study are summarized in table 2. Note that the number of donors to which the recipients were exposed varied greatly according to the type of transfusion received. Thus, on the average, the recipients of whole blood alone were exposed to the risk of contracting serum hepatitis from one or more of 3 donors, whereas those who received plasma only were exposed to the risk of contracting hepatitis from any one of 41 donors. These are average values, but they serve to illustrate how the risk of contracting hepatitis is compounded as the number of donors to which the recipient is exposed increases. Direct comparisons of the crude attack rates, therefore, are not sound because they fail to take into account donor exposure. Accordingly, calculations have been made of the number of cases which might have been expected to occur in each of the groups receiving plasma. These expectancies are based on average probabilities which are derived from the experience of those patients who received whole blood and no plasma. These "expected cases" represent the number which would reasonably be anticipated had each donation of plasma to a pool retained the same chance of infectivity as blood from the same donor population. The expectancy rates are shown in table 2, and, since their derivation is of some importance, the procedure used is given in detail under Calculation of Expected Cases.

The findings are definite and clear cut. Among the 305 surviving recipients of plasma alone, there might have been expected 48 cases of hepatitis if the plasma had not been processed as described. Not a single case occurred in this group, an outcome which can be conservatively attributed to chance less than once in 1,000 times. Similarly, among the 653 recipients of both blood and plasma, 21 cases of hepatitis were observed. The expectancy for this group was 123 cases, 24 of which could be ascribed to the amount of blood which was transfused. Thus, the 21 cases encountered in this group did not exceed the number expected from blood alone. In other words, over a 15-year period, our plasma subjected to storage in the fluid state for six months at temperatures ranging from 76 to 96 F has not been incriminated as the source of a single case of serum hepatitis. In fact, regardless of the greater donor exposure of the patients receiving plasma, it has produced no more hepatitis when given with blood than would be expected from blood alone.

Calculation of Expected Cases

Because the recipients of plasma were exposed to blood from many more donors than those who received blood alone, the risk of acquiring serum hepatitis among them is greater than is immediately apparent. Any calculation of the number of cases which might be expected to occur must take into account not only the number of recipients but also the number of donors to which each of the recipients was exposed. The expected number of cases shown in table 2 were calculated on the basis of average probabilities derived from the experience of those who received transfusions of blood alone.

In order that these expectancies might be calculated, four assumptions have been made: 1. The plasma which was made from unselected, outdated blood was representative with respect to infectivity for serum hepatitis of all blood drawn in this blood bank. 2. The experience of the 21% sample of fully investigated recipients of whole blood was representative of the experience of the 11,382 patients who received transfusions of blood but no plasma. 3. Infectious blood from one donor is sufficient to contaminate an entire pool of plasma. 4. Twenty-two per cent of recipients of infectious blood develop serum hepatitis with recognizable jaundice (a probability of 0.22). Assumptions 1, 2, and 3 require no comment. Assumption 4 is based on the study of Sborov and associates,[2] who investigated the incidence of serum hepatitis among soldiers who received infected plasma in Korea.

The first step in the calculation of expected cases is to determine the probability of blood from a single donor being infectious. This may be derived from the experience of those who received transfusions of whole blood. The basic data and calculations are as follows: total number of recipients of whole blood, 1,894; average number of donors per recipient, 3; number of certain cases of serum hepatitis, 36; and estimated number of recipients of infectious blood (see assumption 4), 164 (36 × 100 ÷ 22). The probability of the patient's receiving infectious blood is therefore 164 ÷ 1,894, or 0.087 (87 chances in 1,000), and the probability of his not receiving infectious blood (1 — 0.087) is 0.913.

TABLE 2.—*Patients, Donors, and Risk of Serum Hepatitis with Transfusion of Plasma and/or Whole Blood*

		Donors		Cases of Serum Hepatitis		
				Observed		
Group	Patients, No.	Total No.	Av./Patient	No.	%	Expected No.*
1. Plasma only	305	12,345	40.5	0	0.0	48
2. Plasma plus whole blood	653	40,841	62.5	21	3.2	123
Blood		3,706	5.7			24
Plasma		37,135	56.9			118
3. Blood only	1,894	5,626	3.0	36†	1.9†	36
				8‡	0.4‡	
				44	2.3	

* Number of cases which would be expected to occur if plasma had same infectivity as blood from which it was processed.
† Certain.
‡ Possible.

But, on the average, these patients received blood from three donors. This means that 0.913 is the probability of not receiving infectious blood from any of the three donors. The probability of not receiving infectious blood from a single donor is the cube root of this value, or 0.97. It follows that the probability of receiving infectious blood from one donor is (1 — 0.97) or 0.03 (three chances in 100, or 3%). This is the probability of blood from a single donor being infectious.

Having determined this probability, it is now possible to calculate the probability of a patient's receiving infectious blood or plasma if transfusion is done with material from any specified number of donors. This is most readily calculated by finding the probability that all donors are noninfectious and subtracting this value from unity. The pertinent calculations in the present study are given in table 3.

The probabilities in table 3 will permit us to calculate the number of cases of hepatitis which would have occurred among those who received plasma if the plasma had not been processed to render it noninfectious.

Group 1.—A total of 305 patients received plasma only from 41 donors, on the average, so that the probability that at least one of these was infectious is $(1 - q^{41}) = 0.712$ (71.2%). The probability of a recipient being susceptible is 0.22 (see assumption 4). Therefore, the expected number of cases is 48 ($305 \times 0.712 \times 0.22$).

Group 2.—First, in regard to the cases expected from both blood and plasma, a total of 653 patients each received blood from 63 donors, on the average. Therefore, the probability that blood from at least one of these donors was infectious is $(1 - q^{63})$ or 0.853 (85.3%). The probability of a recipient being susceptible is, as before, 0.22 (see assumption 4). Therefore, the number of expected cases is 123 ($653 \times 0.853 \times 0.22$).

Second, whole blood alone given to this group came, on the average, from six donors, so the probability that blood from at least one of the six was infectious is $(1 - q^{6})$ or 0.167 (16.7%) and the expected number of cases is 24 ($653 \times 0.167 \times 0.22$).

Table 3.—*Probabilities for Infectivity of Transfused Blood or Plasma*

	Probabilities				
No. of Donors per Recipient	All Donors Noninfectious		One or More Donors Infectious		
1	(q)	0.970	$(1\text{-}q)$	0.030	(3.0%)
3	(q^{3})	0.913	$(1\text{-}q^{3})$	0.087	(8.7%)
6	(q^{6})	0.833	$(1\text{-}q^{6})$	0.167	(16.7%)
41	(q^{41})	0.288	$(1\text{-}q^{41})$	0.712	(71.2%)
57	(q^{57})	0.176	$(1\text{-}q^{57})$	0.824	(82.4%)
63	(q^{63})	0.147	$(1\text{-}q^{63})$	0.853	(85.3%)

Third, the plasma given to this group came, on the average, from 57 donors, so the probability that blood from at least one of these was infectious is $(1 - q^{57})$ or 0.824 (82.4%) and the expected number of cases is 118 ($653 \times 0.824 \times 0.22$).

There were 21 observed cases among this group of 653 recipients. These can all be accounted for on the basis of infection from the blood transfusions, and it is not necessary to assume that any were acquired from transfusions with plasma. The total expected number of cases in this group was 123, which is less than the sum of the 24 from blood and the 118 from plasma. This apparent discrepancy comes from the fact that in these calculations it was possible for persons to be infected from either or both blood and plasma.

Comment

The fortuitous circumstances which led us to propose the value of this method for the processing of pooled plasma as a means for minimizing or eliminating the risk of transmitting homologous serum jaundice were described in 1950.[1a] In order to prove this thesis, it has been necessary to enlarge our clinical experience in order to rule out by statistical tests the possibility that the same results could be obtained by chance alone. There are a number of methods which can be applied to achieve this purpose. We have, in fact, attempted a variety of procedures for computing expectancy rates from our plasma, only one of which is reported here (see Calculation of Expected Cases). Another is an extremely conservative, highly complex method and will be reported as a statistical model from which the most rigorous testing of the safety of our plasma can be made.[3] However, all of these methods led to the same general conclusion, namely, that donations used as blood carry a greater risk of producing homologous serum jaundice than those processed and administered as pooled plasma.

However strong this conclusion may appear to be, it cannot be interpreted to apply to circumstances other than the two specific ones which apply to our experience: First, the product has been maintained in a fluid state with a holding period of six months, although in our experience it has been often somewhat shorter and occasionally longer according to fluctuations in clinical demands. Second, an effort is made to maintain a temperature range which is consistently higher than ordinary room temperature throughout the six months; a conscious effort has been made by us since 1950 to sustain the temperature at 89 F. During the past year, constant temperature storage facilities have been acquired to effect better control. An example of the importance of temperature control and the striking of the correct balance between storage time and storage temperature is our experience with a pool of plasma purchased from another blood bank. In that blood bank it is standard procedure to store the fluid plasma for 12 months at ordinary room temperature before use. Because our plasma supply was exhausted, we obtained and used a pool of plasma from this outside source after it had been stored for only seven months. Forty-two patients were given transfusions with the plasma of this pool, and seven developed hepatitis with jaundice. Temperature measurements in the storage room of the other blood bany averaged 72 F (22.4 C), about 10 C lower than we have employed. Therefore, it is our belief that storage at ordinary room temperatures necessitates a longer holding period to render the plasma noninfective, a view which is consistent with knowledge about decay in virus activity in relation to temperature.[4]

Another episode has also come to our attention since these studies were completed. Recently, two cases of viral hepatitis occurred after transfusions with plasma prepared in our blood bank. In both instances the plasma had been prepared under a modification of the usual temperature and holding period. Each patient was exposed to a different pool, and no cases occurred among the other recipients of these pools. These cases may be ascribed to errors in judgment in efforts further to improve the processing of plasma or to the coincidental occurrence of infectious hepatitis. The latter is an ever-present potential that will eventually occur and tend to confuse the interpretation of cases when the same procedure has been successfully used for many years.

It is important that this report not convey the impression that the current procedure and findings are new, as interim previous reports have appeared from this laboratory since 1950.[5] Similar findings have also been reported by Hoxworth and Haesler.[6] However, the details required for us to complete a full and accurate analysis of clinical material from which reliable statistical computations could be made have only been possible during the past three years. This study has proved worthwhile, for it is now possible to demonstrate that the risk of transmitting serum hepatitis from pooled plasma can be overcome by this simple processing procedure under the circumstances detailed. The proteins of plasma so treated are not disturbed sufficiently to affect their usefulness in the treatment of hypovolemic shock or hypoproteinemia,[7] and there has been no clinical evidence that this product is antigenic. If desired, the product may be subjected to lyophilization satisfactorily after processing is complete.

The obvious importance of the control and detection of bacterial contamination does not present insurmountable problems, but such controls are imperative. As Hoxworth and Haesler [8] have shown, bacterial-restraining filtration may prove useful in reducing the loss of plasma from contamination.

Summary and Conclusions

Follow-up studies were done in three categories of patients who received transfusions at the University of Chicago: those receiving pooled plasma without whole blood, those receiving plasma plus blood, and those given blood without plasma. Complete follow-up studies were possible for 98% or more of the patients comprising each group.

The findings disclosed the following attack rates for serum hepatitis, with jaundice, compared with the number we should have encountered had our pooled plasma been infectious (icterogenic): In the group receiving pooled plasma without blood no cases occurred, whereas 48 would have been expected. The established attack rate for those receiving plasma plus blood was 3.2%, 123 cases would be expected in this series, with 24 from blood received; 21 cases were found, or approximately the number expected. The attack rate among the group receiving blood without plasma was 2.3%; in this group, the average patient was exposed to 3.0 units of blood, whereas the blood exposure for those in the group receiving plasma plus blood was 5.7 units, irrespective of the plasma that was also given. The slightly higher attack rate for the plasma plus blood group compared with those receiving blood alone was therefore to be expected. The pooled liquid plasma was not to be incriminated in any patient as the cause of serum hepatitis.

The probability that the results obtained in this clinical study could have occurred by chance alone, computed statistically, proved to be less than 1 in 1,000. The statistical method reported in this study is but one of several which were applied; regardless of the method used, the conclusions remained unchanged.

There is very little chance that pooled liquid plasma will produce serum hepatitis after being stored approximately six months at an average temperature of 89 F (31.6 C). Provided adequate bacteriological safeguards are used to insure sterility, this procedure will enable the preparation of pooled plasma which is essentially free from the risk of transmitting serum hepatitis.

When these same conditions prevail in plasma preparation, except that the temperature is 9.2 C lower (22.4 C, or 72 F), serum hepatitis can be transmitted despite a seven-month period of storage. Daily temperature records are therefore essential to the safety and success of the procedure we have used.

THE PHYSICIAN HIMSELF

Charles E. McArthur, M.D., Olympia, Wash.

We have come to this scientific assembly primarily, it is true, to learn what we, as physicians, can do to improve the care we give our patients. Little thought and less effort have we given to the maintenance of the health of the individual who is to render these services to the sick. It is of the physician himself I speak. We, as individuals, should be interested to some extent in promoting our own health, and we do care, more than our health record would indicate. There are some among us, as well as among our critics, who would condemn such effort to better our own health record as a selfish endeavor. Yet, if by giving thought, we could add only one year to the working life of the American physician we would conserve more than 200,000 work-years. From the standpoint of good medical care, these years would be the most valuable years of a doctor's career—the product of the perfection of medical skills and judgment based on a lifetime of experience. The economic and medical implications of this added year would be equivalent to adding approximately 7,000 highly trained and experienced doctors to our medical task force.

The fact that the medical profession as a group has a higher mortality from heart disease than its counterpart in the general population should give cause for serious reflection. Nervous strain may well be a factor in the higher heart disease mortality. Another possible explanation for the poor record of physicians as far as heart disease is concerned is the lack of daily physical exercise. The problem must be worked out by each individual physician. First, establish a way of life that includes reasonable respect for your own health. Make regular daily exercise a part of your routine. If nervous tension cannot be avoided, compensate with adequate vacations. Finally, have a physical check-up each year.

"A Yearly P. E. for Every M.D."

In 1955, at the Atlantic City convention, I initiated a project to promote a yearly physical examination for every physician. With the help of members of the Academy of General Practice and with the cooperation and assistance of Fellows of the American College of Cardiology we were able to run electrocardiograms and provide heart consultations on more than 1,000 physicians that first year. Through the help also of the National Tuberculosis Association, chest photofluorograms were made on approximately the same number of doctors. These films were shown to the physician-patients by Dr. Julius Wilson of the American Trudeau Society. Dr. Wilson discussed their findings with all who wished to consult with him.

The number of physicians seeking even this small start on a physical examination confirmed my belief that physicians, especially those from the smaller communities where they live, so to speak, in glass houses, welcomed an opportunity to be examined by and consult with a physician who was a stranger. During the past three annual sessions of the American Medical Association, we have made approximately 3,000 electrocardiograph tracings and chest photofluorograms on physicians. This has been primarily a service project. An analysis of the findings is shown in the table and in figure 1. Our facilities have been limited and the surroundings crude and bare, certainly, as compared to the plush and ultramodern private offices we provide for our patients. But in spite of these handicaps, few and only minor errors occurred. Credit must be given to the dedicated cardiologists who devoted their time and skill to interpreting the electrocardiograms and to consultation with the physician-patients.

Of the first 3,228 electrocardiograms, we found nearly 18% to be either definitely abnormal or borderline. Chest photofluorograms were taken of somewhat fewer (2,749) physicians. These showed about 15.5% suspected or definite abnormalities, including, in addition to tuberculosis, chest neoplasms and cardiovascular abnormalities. Unfortunately, we were unable to correlate the heart examinations with the chest films. Many who had electrocardiograms did not have chest films, and we found that some who showed evidence of heart disease on the chest film had not had electrocardiograms.

Previous Studies on Physicians' Health

Master, Chesky, and Pordy,[1] in 1951, reported a study on 200 physicians. It is interesting to note that they found approximately 15% abnormal electrocardiograms. While we have no comparable studies on the general population with which to compare our findings, we do have the work of Dublin and Spiegelman[2] who, in 1947, published figures on longevity and mortality of physicians. These showed a higher annual death rate for phy-

---

Chairman's address, read before the Section on General Practice at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

sicians than for their counterpart in the general population. This was strikingly evident for the leading cause of death, viz., diseases of the heart and coronary arteries. The recorded death rate for physicians from these diseases was 1.8, or nearly double, that of white males of the same age groups in the general population.

Results of Chest X-rays in Physicians at A. M. A. Annual Meetings

Results	1955 No	1955 %	1956 No.	1956 %

In 1956, Dickinson and Martin[3] reported a more favorable death rate from all causes for physicians as compared to their corresponding age groups in the general population, but, again, for the leading cause of death, heart disease, physicians still led by an uncomfortable margin. In 1948, Dublin and Spiegelman,[4] in a report on mortality of specialists, further pointed out that the over-all mortality of specialists was approximately 30% less than for general practitioners. Conceivably the great increase in specialization or limited practice could account in some degree for the more favorable death rate reported by Dickinson and Martin a decade later.

The Problem

The problem is, why should physicians as a group have a higher mortality from heart disease than the general population, and why should the family physician have a higher mortality than the specialist? The factors involved in both questions are probably much the same but vary in degree. There are a number of factors operating to a greater or less degree in various areas.

City Versus Country Doctors.—Dublin points out that the specialists are concentrated in the urban centers where they have the advantage of large hospital facilities and also that the larger income which they enjoy permits them to take better care of themselves by taking frequent and longer vacations. Another explanation may be that the man in the large city has an opportunity to consult with a doctor who is relatively a stranger. (The man one calls a friend in a metropolitan area would be classed as a mere passing acquaintance in the social life of the small community.) The physician in the smaller community hesitates to consult a local colleague because, as mentioned before, he lives in a glass house. He must conceal his illness and camouflage his fatigue. Further, the family physician in the smaller community has an abiding loyalty and sense of obligation to his patients. The vacation he plans is so often put off year after year because of a maternity case or any one of a myriad of circumstances. The years fly by and suddenly heart disease, today's "captain of the men of death," bars the way. The vacation is never taken.

Specialist and Family Physician Compared.—The specialist has another advantage in working by appointment and seeing a restricted range of diagnostic problems. This surely makes for less nervous strain. The number of patients that the family physician must see and the variety of diagnostic problems results in a nervous strain that is peculiar to this type of practice. For one-half day each week, I practice as specialist. For years, I have reserved one morning each week for maternity patients whom I see by appointment. If you don't do so now, I suggest that you try it. The marked reduction in nervous strain in seeing only one type of patient and the more or less leisurely schedule that allows one to sit down and talk with the patients unhurriedly and to examine them as you feel that you should is almost as relaxing as a day off.

Factors Related to Heart Disease

Nervous Strain.—Nervous strain may well be a factor in the higher heart disease mortality of physicians as compared to their counterpart in the general population, and for the family physician as compared with the specialist. It is interesting to note here that Dublin and Spiegleman found that internists and pediatricians were the only groups who had better mortality figures for heart disease than that for all physicians and that surgeons had as poor a record as the average for all physicians. Nervous tension (fig. 2) is doubtless an occupational hazard of our profession. I cannot imagine caring for the desperately ill without worrying. If I were ill, I would certainly want the physician

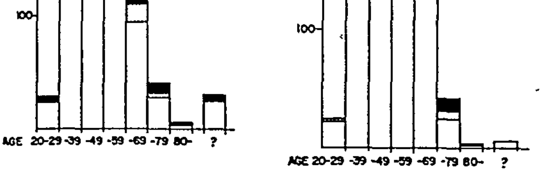

Fig. 1.—Results of electrocardiogram tracings (*left*) in 1,017 physicians in 1956 and (*right*) in 992 in 1957.

who treated me to be a bit worried. But the lack of adequate vacations is inexcusable (fig. 3). It is the result of poor planning or perhaps a very human failing of feeling indispensable. Adequate vacations would compensate to some degree for the nervous strain under which we must work.

Fig. 3.—Vacation is postponed.

Daily Exercise.—Another possible explanation for the poor record of physicians as far as heart disease is concerned is the lack of daily physical exercise. None of us is so naive as to think that the family physician has opportunity for any regular physical recreation. Some participate, it is true, in some type of sports or other physical recreation, but if we are honest about it, we must admit that it is sporadic and probably of doubtful benefit or perhaps even harmful. Yet, the physician, if he wishes to improve his mortality record, must secure regular daily exercise (fig. 4). How can this be done? It is not impossible if we avail ourselves of such opportunity as comes to hand. For example, if you walk up only six flights of stairs each day when you make your hospital rounds, instead of riding the elevator, you will expend approximately 9,000 foot-pounds of energy, over and above that involved in ordinary walking. This is not as much fun as a game of golf, or tennis, or handball, but these are exercises one cannot do every day. You can hike up those stairs at least once a day, seven days a week, securing that badly needed daily bout of exercise, and you will be in better shape for that game of golf when and if you get a chance to play it. Exercise and physical recreation are serious deficits in the daily lives of most physicians.

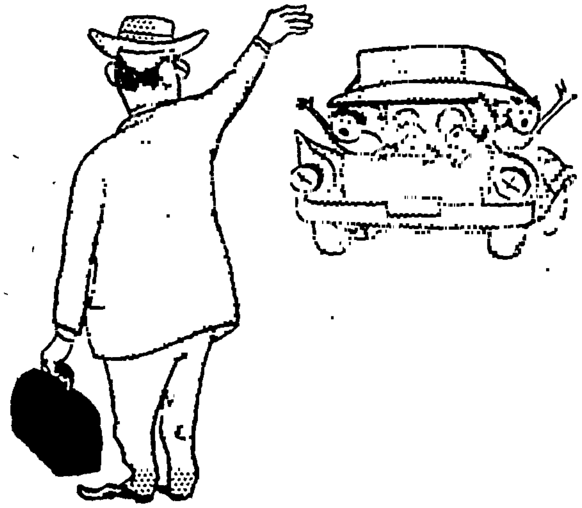

Fig. 2.—Nervous tension, an occupational hazard.

Faulty Diet and the Blood Lipids.—In recent years, considerable attention has been focused on faulty diet as one of the causes of increased death rates due to heart disease. To what extent diet is a factor in the higher mortality rate due to heart disease among physicians as compared with the general population is only speculative. The irregularity of our meals with the resultant lack of variety in available food may be significant. But we do know that the incidence of coronary thrombosis is much greater in individuals with elevated serum cholesterol levels. It is certainly prudent then for every physician to periodically check his blood cholesterol or blood lipid level and, if elevated, take steps to reduce it (fig. 5).

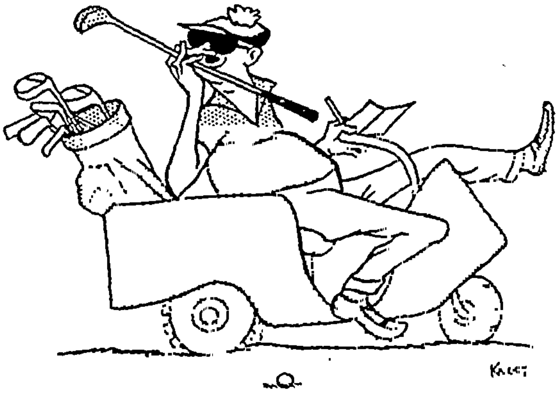

Fig. 4.—Regular daily exercise—serious deficit in lives of most physicians.

Much is said about the high fat content of our diets, but little has been said about the evil caused by concentrated carbohydrate in our foods[5] or about their possible relationship to hypercholesteremia or hyperlipidemia.[6] The prevalence of atherosclerosis in diabetics, with their deranged carbohydrate metabolism, is well known. It is common knowledge that as long as sugar is available it will be burned in the body and the fat and protein will be stored. When sugar is not available, protein and fat are oxidized to furnish the body's energy requirement. For some time I have suspected that the concentrated carbohydrates of our present day diet might be one of the factors in atherosclerosis. For that reason, when I have a patient in whom either the cholesterol or serum lipoprotein level remains elevated, in spite of the conventional low fat or low caloric diet, I place him on an extremely low carbohydrate diet (approximately 20 to 30 Gm. of carbohydrate daily). This figure can be attained not unpleasantly by placing the patient on a diet

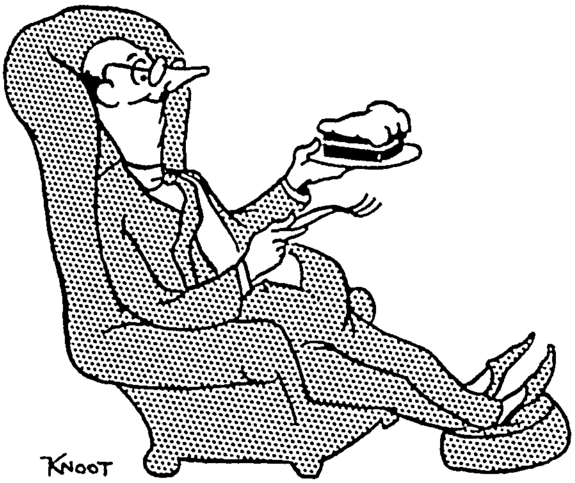

Fig. 5.—Faulty diet and high blood lipid levels.

of lean meats and vegetable salads, using a vegetable oil, such as corn oil, to make the salad dressing. In each and every case, there has been a sharp fall in the blood cholesterol level.

Figure 6 illustrates one such case. There was poor control of cholesterol level in this case, in spite of a low fat diet. The high point of 477 mg.% was taken at a time when the patient was under an emotional strain. There also had been a marked increase in the carbohydrate intake in the several weeks before the high cholesterol reading was obtained. The patient was placed on a high protein and extremely low carbohydrate diet; the result is clearly shown. There was no significant change in the fat intake. If any of you have trouble keeping blood lipid levels down on the conventional low fat diet, try this simple one. I think you will be surprised. Whatever the diet, the point that should be stressed is that physicians, too, should check the effect of diet on their own blood cholesterol level. It may be higher than you think.

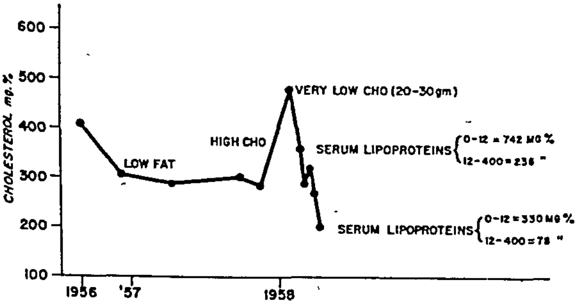

Fig. 6.—Diet and blood lipid levels.

Summary and Conclusions

The problem of heart disease is an individual one, and the solution must be worked out by each individual physician. First, establish a way of life that includes reasonable respect for your own health. Make regular daily exercise a part of your routine. If nervous tension cannot be avoided, compensate with adequate vacations. Check your diet against its effect on your weight and on your blood lipids. Finally, have a physical check-up each year. The amount of unsuspected pathology uncovered during the limited examinations we have done these past three years should convince anyone that physicians, too, should have physical check-ups. Your own self-examination should be supplemented by periodic objective examinations including electrocardiograms, x-rays of the chest and gastrointestinal system, proctoscopic examination, and such other examination as may be indicated (fig. 7).

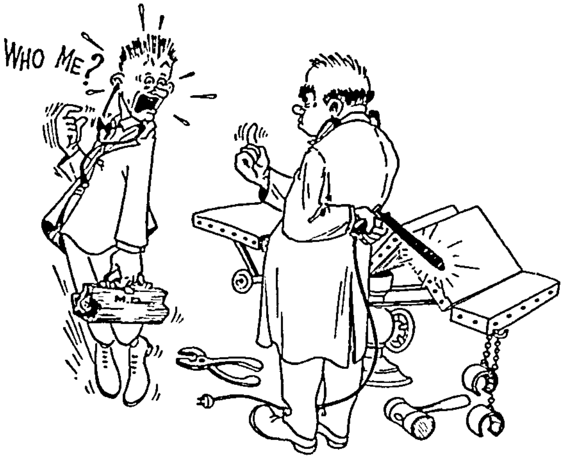

Fig. 7.—Yearly physical examination, including proctologic examination.

In conclusion, the fact that the medical profession as a group should have a poorer mortality from heart disease than their counterpart in the general population should give cause for serious reflection, for, in fact, each one of us has a physician in attendance 24 hours a day. If medical knowledge is worth anything at all, and if properly applied to ourselves, the health record of the medical profession should be far superior to that of the general population.

The life of the dedicated physician is a life of service to others. The physician today, as for untold generations, is a victim of circumstances and pressures of his calling. Some, by reason of good fortune, will have good physiques, and boundless good health will be theirs in spite of all manner of neglect. Others, because of misfortune, will die prematurely in spite of the best of care. But the majority of us will live longer and render more and better service to our fellow men if we will periodically turn our attention and skills to maintaining the physical and mental health of the physician himself.

RESEARCH ON HUMAN FACTORS OF AERIAL WARFARE

Col. John P. Stapp (MC), U. S. A. F.

New problems of adaptation and protection for men in stressful environments have resulted from the increasing range and velocity of aircraft. Extremes of pressure, temperature, acceleration, radiation intensity, monotony, isolation, and suddenness of change are encountered in aviation and must be reproduced in the laboratory. An arduous program of research must be accomplished before manned satellites can be sent into orbit, but it is a magnificent challenge and offers the likelihood of countless unforeseeable but valuable results.

Aviation medicine had its beginning in World War I, when the airplane evolved into a fighting machine. The U. S. Army's physical examination was modified by trial and error into a flying physical examination for selecting candidates for flying training. Continued development in aircraft speed, altitude, and range, along with expansion of the Air Corps, justified special training of doctors in the selection and preventive maintenance of flying personnel: These were our first flight surgeons.

In the decade after World War I, the School of Aviation Medicine was established at Randolph Field, Texas, to train flight surgeons and to carry on research on the care of the flyer.

Emphasis was on sensory and neuromuscular adaptation to three-dimensional orientation required for flight. In the decade preceding World War II, aircraft could reach altitudes that threatened loss of consciousness from lack of oxygen and could attain velocities that offered a threat of blackout by accelerations in turning maneuvers that arrested cerebral circulation. Flight became difficult in open cockpits because of increased wind-stream pressures at higher speeds and lower temperatures at high altitudes.

These factors called for research and development to determine human requirements in the aerial environment and to provide protection from its adverse factors. For this mission, the Aero Medical Laboratory was established at Wright-Patterson Air Force Base, Ohio, in the Aeronautical Research Division of the U. S. Army Air Corps. Doctors, physiologists, and psychologists flew to observe and record the factors of the aerial environment in flight. These factors were then reproduced in ground-level simulators for controlled experiments.

The altitude chamber was designed to reproduce the decreased density of air at any given altitude above the earth. With it, animal and human reactions to decreased oxygen tension were studied extensively. Such studies made possible the development of the oxygen mask to supplement air breathing from 10,000 ft. up and to provide total oxygen requirements above 30,000 ft. This extended human performance to match aircraft altitudes. Blackout, manifested during pull-outs from dives or tight turning maneuvers at high speeds, was reproduced on the ground by the human centrifuge. This was a carousel-sized version of the laboratory centrifuge commonly used to separate corpuscles from plasma

---

Read before the Section on Military Medicine at the 107th Annual Meeting of the American Medical Association, San Francisco, June 27, 1958.

by radial acceleration. A volunteer subject exposed on this device to forces identical with those encountered in airplane maneuvers experienced the same loss of peripheral and central vision, terminating in loss of consciousness when the force exceeded four and one-half times gravity for more than three seconds. This force was accurately measured in terms of the earth's gravitational field as a unit. The acceleration of gravity pulling the body downward against the resistance of the spring in a bathroom scale will register a force equal to the body weight in pounds. On the centrifuge, a 160-lb. (72.6-kg.) man will be pressed into his seat with a force equivalent to four and one-half times his body weight, or 720 lb., at blackout. By offsetting arterial hydraulic pressure pumping blood to the brain, this force deprives the retinas and cerebrum of oxygen, with consequent loss of consciousness.

Military Aviation Medicine

Early in World War II, aviation medicine expanded with the growth of military aviation. Laboratories under direction of the U. S. Navy at Bethesda, Md., and Pensacola, Fla., and of the Mayo Clinic at Rochester, Minn., made great contributions. The problems of human maintenance in aerial combat in every climate from arctic to tropics, of parachuting, land survival, and sea survival, were pursued by these laboratories. Simultaneously, they accomplished a gigantic training program to supply flight surgeons, flight nurses, technicians, and aviation physiologists to meet combat and indoctrination requirements. They contributed to one of the major achievements of aviation medicine in World War II—development of air evacuation of the sick and wounded.

Unpressurized, open-window bombers led to the development of electrically heated suits, predecessors of the familiar electrically heated blanket. Prolonged high-altitude missions introduced the problem of high-altitude bends, accelerating the development of the pressure suit. The pressurized cabin bomber removed the hazard of bends but replaced it with the no less formidable one of explosive decompression. Antigravity suits to protect fighter pilots against blackout by counter pressure to blood reservoirs in the legs and lower abdomen were invented and tested with the centrifuge.

Scarcely had the problems of piston engine aircraft been mastered when the advent of jet engine aircraft introduced an entirely new spectrum of difficulties. Foremost of these was the problem of escape, no longer possible by simply crawling out of the cockpit and parachuting down, as in the case of damaged piston engine aircraft that had to be abandoned in flight. Ejection seats, first invented by the German Air Force, were taken over at the end of World War II and perfected by the U. S. Air Force and Navy aero medical laboratories. Jet fighters rapidly attained supersonic speeds, further complicating the pilot's problem of coping with demands on his attention and reaction to flight situations. Escape had to be made fully automatic in the face of evidence that, once the protection of the canopy was removed, the dazed and buffeted escapee was helpless to discard the seat and actuate the parachute. The inexorable demands of incessantly higher and faster jet and rocket-powered aircraft were successive turnings of the screw, ever tightening the demands on human quickness, coordination, endurance, emotional stability, and tolerance to stress.

Physiology of Stress

Out of the background of medical physiology and psychology of the normal man at rest and at work, out of the physiological pathology of disease and injury, comes a new approach to meet the needs of jet and rocket age man—the physiology of stress.

Combining the techniques of physiology, physiological chemistry, biophysics, and psychology, this new field of research proposes to find in quantitative terms the limits of tolerance, adaptation, and ability to perform under stressful conditions up to the ultimate.

In the laboratories of aviation medicine maintained by the U. S. Air Force and Navy, there has arisen a unique tradition and even virtuosity of experimenting with human volunteers; they submit to painful, fatiguing, and hazardous procedures of applied research in pursuit of answers on which the lives of combat personnel will depend.

Where knowledge so obtained has vital civilian applications, as in the case of deceleration experiments on tolerance and survival of crash forces, applicable to civilian air transport and automobile safety design, such information has been made freely available to the respective industries and has been made the basis of design specifications for seats and belts.

Volunteers for hazardous experiments enjoy economic and medical protection developed within the service to cover the exigencies of combat. Indeed, the diplomatic cold war and its pressures on weapons developments becomes a hot war in the laboratories, where lives are risked in research on human factors of aerial welfare.

Space Medicine

Gradually, and with little premeditation, aviation medicine research has laid the groundwork for space medicine. Most of the problems of space medicine are but extensions of the same problems of aviation into space dimensions. Projecting from the brief exposures to acceleration endured in airplane maneuvers, seconds of exposure turn to minutes of high acceleration during the stages of space missile propulsion to attain fantastic velocities for going into orbit or for escaping from the earth's gravitational pull.

The centrifuge, which in the days of airplane research exposed volunteers to seconds of blackout acceleration, is now called on to spin them for minutes of rocket acceleration at even higher decelerative forces, which can only be withstood by presenting the body in a semirecumbent position on a bed-like, flattened contour chair, at right angles to the line of force, from front to back.

With finger controls, the subject, his arms immovable from the pressure of 8 G, is able to maintain a dot on a crosshair target for more than two minutes. Only at 12 G, in this favorable position, does he black out as blood is pushed back from the retinas.

Reentry into the earth's atmosphere from orbiting flight might require many minutes of exposure to decelerations of aircraft blackout magnitude. On the centrifuge, human volunteers have withstood 3 G for one hour in the transverse, semirecumbent position. If this were a constant vertical acceleration at 3 G for one hour, the final velocity would exceed 200,000 mph, or eight times the speed required to escape the earth's gravitational field. At 4 G, the centrifuge exposure could be tolerated for less than an hour because of uncomfortable effect in breathing.

One problem defies ground level simulation. Entry into orbital flight relieves the body of all accelerative force. The rate of turn in the orbital ellipse exactly equals and is opposite to the acceleration of gravity, so that the capsule and its occupant are in a weightless state.

On the ground, underwater flotation of the body allows limited imitation of weightlessness, useful in certain neuropsychiatric experiments. Only by taking a fast jet aircraft up to 30,000 ft. and putting it through a combination shallow outside loop and dive, where the combination of radial acceleration and rate of descent can be made equal and opposite to the earth's gravitational pull for 30 seconds or less, can a brief exposure to weightlessness be obtained.

The acceleration of several G required to enter and exit from this maneuver make it impossible to discriminate effects of true weightlessness from the effects of changing gravitational climate. Indications are obtained, however, of subjective and objective alterations of reflex sensations and responses, of adaptations in orientation and equilibration without a gravity reference.

Motion pictures have been made of the comical efforts of subjects to eat and drink in the weightless state. Fluids float in the air in globules that defy corralling; food floats between the tongue and the palate. What was at first considered a significant increase in nausea and vomiting, comparable to airsickness in ordinary flight, turned out to be vomiting and nausea: the subject felt food floating up the esophagus from peristaltic contractions with a relaxed cardiac valve during weightlessness, which set up a vomiting reflex when the bolus reached the pharynx. A purse-string suture around the cardiac sphincter is hardly the answer for this problem.

A more sinister problem is hinted at in an observed decrease in blackout tolerance after the 30 seconds or less of weightlessness. A 4.5-G pull-out at the end of the zero gravity aircraft maneuver resulted in blackout of several times the duration experienced by the same subject after the same pull-out not preceded by exposure to zero gravity. What would abrupt exposure to violent decelerations during reentry maneuvers do to a space pilot with thresholds to acceleration diminished by several hours of adjustment to weightless orbital flight in a capsule, with circulation adjusted to decreased muscle tonus resulting from deprivation of proprioceptive and antigravity reflexes?

This question can only be answered by the first animal and human orbital experiments with successful reentry. The only antigravity machines encountered at ground level are found in the comic sections of the newspapers. They have the advantage of many years dedicated to levity.

Two other factors might have consequences vital to survival in the first manned space flight: deprivation of normal sensory stimuli to which the space pilot is accustomed on earth and isolated confinement in this close-fitting capsule in the darkness and quietness of outer space. Numerous ground simulation experiments have been carried out and are in progress to evaluate human reactions to such conditions. Even the near vacuum of 200 miles above the earth has been reproduced in a chamber on the ground by evacuating it until it is less dense than the contents of a radio vacuum tube. This space altitude chamber aids in the development of pressure suits able to contain viable pressures in case a space pilot must abandon his capsule 200 miles above the earth.

The most definitive human experiments to date on exposure to space equivalent conditions have been accomplished by the U. S. Air Force and the U. S. Navy with helium-filled, plastic, free balloons carrying manned capsules above the stratosphere. At 102,000 ft., the highest altitude thus attained to date, the capsule is above 99.0% of the earth's atmosphere and, essentially, total solar radiation is experienced in the practically nonconducting remainder. Thus, temperatures above boiling on the sunny side of the capsule were measured at the same time temperatures 100 degrees below freezing prevailed on the shady side. Total ultraviolet content of the sunlight, unfiltered by the earth's atmosphere, would make exposure outside the capsule quickly unendurable. At this height the earth's gravitational field is only diminished 1%; therefore, weightlessness played no part in this experiment.

These experiments demonstrate the usefulness of a space platform 20 or more miles up that can remain aloft more than 24 hours with occupants able to maintain themselves and make useful scientific observations.

Conclusions

Long before the first manned missile hurtles into the heavens seeking an orbital path, a long program of arduous, tedious research with the usual quota of trials and errors, of failures and breakthroughs, must be accomplished. Homo sapiens is not going to be converted into "homo spaciens" overnight.

Something more than curiosity, something more than fear of being outrun in the cold war, something more than the foreseeable economic and scientific returns of space flight motivates man into this unknown, toward unpredictable results and unforeseeable consequences. Perhaps when the first man returns from the first successful flight into space, he may find words to tell us how our world looks from his unique point of view. Human progress is marked by increments of objectivity and of projection. What more challenging increment of human outlook than to see our world from the viewpoint of the universe!

PSYCHIATRIC PROBLEMS AND PREFERENCES FOR INSTRUCTION

AN APPRAISAL OF REPORTS BY THREE HUNDRED THIRTY-EIGHT GENERAL PRACTITIONERS

Cecil L. Wittson, M.D., LaVerne C. Strough, M.D.
and
Jackson A. Smith, M.D., Omaha

The interests of nonpsychiatrist physicians in various aspects of psychiatry and their attitudes toward psychiatrists were studied by a questionnaire method, with responses from 338 nonpsychiatrists. In addition, the literature was surveyed for publications on the subject of postgraduate courses in psychiatry for general practitioners. The purpose was to plan more satisfactory courses of this kind and in general to improve the cooperation between nonpsychiatrists and psychiatrists in the management of emotional illness. The results of the study showed that communication between the two groups was not altogether satisfactory. General practitioners varied markedly as to the frequency with which they encountered or recognized psychiatric problems. They were not so much interested in questions in referral as in medical and physical therapy. As to courses of instruction, their preferences were for clinical representations with adequate emphasis on neurology.

In order to more satisfactorily plan postgraduate courses in psychiatry for general practitioners and other nonpsychiatrists, a survey of the literature in this field since 1950 was made and a questionnaire was mailed to over 1,200 practicing physicians to determine their interests.

Review of the Literature

The survey of the literature revealed the majority of the reports were written by psychiatrists; the following points were stressed as problems of major importance for the general practitioner in the management of these patients: a reluctance to accept emotional illness as being primarily a medical disturbance, the existence of similar problems in the patient and the physician, and difficulties in diagnosis. The needs for a more adequate and complete history and more satisfactory methods of referral were emphasized.

This problem of referral by the generalist to a psychiatrist was discussed in several papers. Factors influencing referral but not sufficiently emphasized were (1) the patient's (and the public's) concept of a psychiatrist, (2) a lack of understanding of psychiatric terminology in consultation notes and in case presentations, and (3) the general practitioner's attitude about psychiatry.

The first of these factors, the patient's concept of a psychiatrist, is detailed by Bingham.[1] She pointed out that "though a resident of New York City until

---

Read before the Section on Nervous and Mental Diseases at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

three years ago, I had not only never met a psychiatrist, but I had never met anybody who had met a psychiatrist." She makes the plea that the psychiatrist present himself to the public as a human being who is occasionally baffled by his children and is capable of error, and not an omnipotent, all-knowing person from whom nothing can be concealed.

Second, the problems in communication between psychiatrist and nonpsychiatrist are manifest in the complaint of the general practitioner that he either does not understand the psychiatrist's report or that the report fails to inform him on how to proceed in the management of the patient.

Appel[2] has described a few trends in psychiatric training which may account for some of this difficulty. He points out that "much psychiatric thinking is removed from the readily observable and confirmable to the theoretical" and that "one observes more emphasis on dynamics and increased facility in speculation." Perhaps a major factor has been the tendency for patient examination, case conferences, and formulations to become what Appel describes as "stream of consciousness reports, a la Gertrude Stein or James Joyce." Hypotheses may be asserted as facts or terminology be taken for explanation. Consequently, the general practitioner attempting to explain psychiatric illness, treatment, and prognosis to anxious relatives may be as much perplexed as enlightened by a psychiatric report of the type Appel describes.

The third factor which may influence referral is the general practitioner's attitude about psychiatry. A stimulating report[3] of a panel discussion on this subject merits consideration. The panel was composed of three general practitioners and two psychiatrists.

The generalist's feelings (which might be called negative) about the psychiatrist's frequent refusal of professional courtesy were discussed with some affect. The lack of help or direction the nonpsychiatrist receives with such problems as duodenal ulcer and ulcerative colitis, and the lack of results seen when consultation was requested for such patients, was mentioned. The psychiatrists replied that, in somatic illness where organic change has occurred, the results of psychotherapy were often poor or nebulous and, for this reason, the psychiatrist was unwilling to undertake a long course of treatment which would be expensive to the patient. The general practitioners felt that, as a physician, the psychiatrist should never "throw up his hands" even though the condition was not alterable and that an obligation existed to help the patient live better with his disease.

The point was made, with emphasis, that the general practitioner does not know psychiatrists as individuals, because during residency training they are in a separate building and, when the generalist begins practice, he sees other specialists at lunch, at clinical pathological conferences, and on rounds but he does not see psychiatrists.

The implication was that the psychiatrist was professionally and socially isolated from the nonpsychiatric physician after his internship. The psychiatrists on the panel pointed out that the time required to do psychotherapy was extensive, that no methods were available to offer "quick relief," and that "the tools which we have to work with are limited." The general practitioners' reply was that 60 years ago all physicians' tools were limited but advances had been made.

Although this panel discussion was refreshingly lacking in agreement, and everyone had an opportunity to express his opinion or bias, the feelings expressed by the participating general practitioners would certainly merit consideration by those planning postgraduate courses.

There was general accord in the papers surveyed that the emotionally ill or those with organic illness complicated by emotional factors made up a sizable proportion of all those patients seen in general practice. There was also accord that psychotherapy with the somatically ill was primarily the responsibility of the physician treating the patient for his somatic illness.

Hyde gives an excellent description of the problems the general practitioners may face in the diagnosis and treatment of the mentally ill, based on his own experience in practice. He stated, "Twenty years of seeing the problems of one's patients bring about a richness of perception and understanding that perhaps cannot be equalled by any other system."

Methods of Survey

To determine the interests and preferences of nonpsychiatrists in postgraduate courses in psychiatry, a questionnaire was sent to over 1,200 practicing physicians. This questionnaire contained 21 items to be checked by the physician and was sent by first class mail with an explanatory letter. The questionnaire, a stamped envelope with a return address for use in returning the form, and the explanatory letter were mailed in a folder bearing a University of Nebraska letterhead.

To determine whether those who did not reply failed to do so for a lack of interest in the subject, 40 physicians who did not answer were selected at random and a second letter and the same questionnaires were mailed to this group. The second letter emphasized the importance of their cooperation in the satisfactory completion of the study rather than their interest in postgraduate courses in psychiatry.

Of the responding physicians, less than 2% limited their practice to psychiatry and neurology, while 72% were in general practice and 25% were in other specialties (a few respondents made no indication of type of practice).

Results of Survey

Three hundred twelve physicians returned the first questionnaire; 26 of the 40 who were sampled in the second mailing responded. Apparently they were twice as interested in helping with the study as in postgraduate courses in psychiatry.

In the following data, the differences between the percentages given and 100% were those who left the question blank or checked both possibilities. In the results of the questions as to preference for type of presentation, speakers, clinical material, and method of presentation, 66% preferred a clinical type, 50% preferred local to nationally known speakers, 66% preferred a discussion of case material from the institution where the course was given to a presentation of the speaker's own cases, and 60% preferred several cases briefly presented to one case in detail.

On the questions pertaining to the physician's area of interest (table 1), blanks were provided to allow the respondent to qualify his interest in a given area as "much," "some," "little," or "not at all." The major interest in physical and drug therapy was anticipated, due to the present epidemic of "lost tranquility" and the enduring hope for a rapid method of management.

TABLE 1.—*Physicians' Areas of Interest*

	Degree of Interest, %				Space Left Blank, %
Topic	Much	Some	Little	Not at All	
Physical and drug therapy	66.86	19.82	6.80	0.89	5.63
Diagnosis	60.06	26.92	5.32	2.38	5.32
Psychiatric aspects of family counseling	52.52	27.00	10.09	5.34	5.05
Causes	50.89	28.41	10.65	3.25	6.80
Psychotherapy	45.99	30.56	13.95	1.78	7.72
Neuropsychiatric outpatients	42.90	33.43	11.54	5.92	6.21
Community mental health programs	27.81	30.77	21.79	10.36	9.27
Legal problems in psychiatry	27.51	29.39	21.89	10.56	10.65
Commitment procedures	26.92	27.81	20.42	13.31	11.54
Hospitalized neuropsychiatric patients	7.39	29.29	34.62	16.87	11.83
Referral problems	6.33	44.72	23.21	13.08	12.66

However, it was not anticipated that diagnosis, family counseling, and etiology (causes) would be of more interest than psychotherapy, which is regularly presented as a factor in all types of treatment. The awareness of the importance of family counseling and the acceptance of this activity as a medical responsibility was encouraging. The area of least interest, "referral problems," is emphasized; it was previously mentioned that this was a frequently discussed problem in the literature in this area. Apparently, the nonpsychiatrist has had sufficient instruction on this subject or in any event is not particularly interested in having more.

Results in the third category, frequency of psychiatric problems in practice (table 2), are somewhat unusual, because 38% of those responding saw psychiatric problems in 17% or less of their patients; at the other extreme, 17% saw psychiatric problems in 88 to 100% of their patients. It would seem rather improbable that the patients who compose the practice of the respondents would vary to this degree. It seems more likely that there is little accord as to what constitutes psychiatric problems or that the criteria for such a diagnosis vary rather widely.

Table 3 reveals that only one-fourth of those replying had a marked interest in postgraduate courses in psychiatry but 77% stated they would attend such courses if they found them interesting. Having to travel to a central point to attend such courses was not seen as a handicap, since only 67% were interested in a live two-way broadcast which they could hear locally.

TABLE 2.—*Frequency of Psychiatric Problems in Practice*

Patients Seen with Psychiatric Problems, %	Respondents, %	
0-7	18.64	38.46
8-17	19.82	
18-27	13.91	
28-37	7.69	
38-47	3.55	
48-57	9.76	
58-67	2.96	
68-77	5.31	
78-87	0.90	
88-100	17.46	

The last three replies were somewhat surprising, since a bare 3% preferred courses which emphasized only psychiatry, whereas 12 times as many preferred courses which emphasized only neurology. The majority preferred an emphasis on both subjects.

Comment

The literature reviewed was more an expression of the psychiatrist's view of the general practitioner's problems than opinion of what the general practitioner thought he needed. One report[3] of a panel discussion between generalists and psychiatrists was refreshing in the candor and content of the opinions expressed.

The 338 replies in the survey showed the nonpsychiatrist's interest in somatic and drug treatment procedures and a disturbing 97% lacking interest in courses limited to psychiatry. From the replies, it appears the generalist appreciates the needs of family counseling but has little interest in hearing more about the problems of referral.

The problems of communication between psychiatrists and nonpsychiatrists would appear an area to be considered by those planning postgraduate courses. Although descriptive psychiatry has not been fashionable for some time, a clarification of the signs and symptoms by which those who are emotionally ill may be recognized (as well as the dynamics of their particular case) might make communication less a problem.

TABLE 3.—*Physicians' Interest in Postgraduate Courses*

Degree of Interest	Respondents, %
Marked	25.29
Moderate	43.60
Mild	15.98
Slight	4.44
None	2.66
Blank	5.33
Would attend interesting course	76.92
Two-way broadcast	67.46
Emphasis of course	
Psychiatry	3.16
Neurology and psychiatry	59.49
Neurology	36.71

Summary

On the basis of 338 replies to a questionnaire, the following preferences and interests of nonpsychiatrists were determined: General practitioners preferred clinical presentations, local speakers, a presentation of patients from the institution where the course was given, and several cases briefly presented. Their greatest interest was in physical and drug therapy; they were least interested in problems of referral.

A marked discrepancy in the frequency with which psychiatric problems were seen in their practices was reported; 38% saw such problems in less than 17% whereas 17% saw the same problems in more than 88% of their patients.

Only one-fourth of the physicians who replied checked a marked interest in postgraduate courses in psychiatry, although 77% would attend if such courses were interesting. Ninety-seven per cent did not prefer courses with an emphasis only on psychiatry.

602 S. 44th Ave. (5) (Dr. Smith).

This study was supported in part by the Nebraska State Department of Health and the Board of Control Psychiatric Research Fund.

WHIPLASH INJURIES

NEUROPHYSIOLOGICAL BASIS FOR PAIN AND METHODS USED FOR REHABILITATION

Emil Seletz, M.D., Beverly Hills, Calif.

The collision of automobiles generally results in either acute flexion or severe hyperextension of the passenger's neck, depending on the direction of the impact. Direct trauma results to the spinal accessory nerve and to the roots of the cervical nerves, but in addition there are vasomotor disturbances resulting indirectly from damage to the vertebral arteries and to nerve fibers that accompany these arteries in their course through the foramina transversaria. The result is a varied syndrome of neurological and neurovascular troubles. Treatment with tranquilizers and psychotherapy is of no avail, and patients become discouraged and resentful. The procedure here outlined includes heat, manipulation, and traction. Carefully adapted to the individual case, this plan generally obviates the danger of surgical and psychiatric complications and often leads to prompt rehabilitation of the patient.

Our present industrial civilization religiously follows the creed to serve only youth and its irresponsibility. There is no way to avoid the ever-increasing incidence of whiplash injury. It is not within the realm of the physician to even talk of the prevention of these injuries, since the basic goal of our mechanical progress is to increase the "force of thrust," accelerate speed, and achieve absolute automation. The only way to protect man against his inventive genius is to encase him in stainless steel armor, which is more fitting today than in the days of King Arthur.

In order to properly help with this problem we must change our basic concept of this injury, for it is not a direct injury only to bony architecture and soft muscle structures. While, occasionally, after whiplash injuries to the cervical spine, the x-rays may reveal injuries to bones or joints with possible dislocation or subluxation, the disabling and persistent symptomatology in the vast majority of cases is due to involvement of the delicate and vital nerves and blood vessels about the cervical spine.

A varied and complex neurological and neurovascular syndrome so consistently follows the major type of neck sprain as to constitute a definite syndrome. Since a great percentage of the symptoms are referred to and arise from disturbance of the central nervous system, I have chosen to name this the "craniocervical syndrome." [1]

Read before the Section on Physical Medicine at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

Since the x-ray findings in this syndrome usually splay no bony injury, many of these patients are cused of having functional disorders and eventu-ly go to psychiatrists instead of to those expertly ained in physical medicine and rehabilitation, who operly should treat these patients.

The purpose of the present communication is two-ld: (1) to determine the neurophysiological basis r the pain and disability; and (2) to stress the portance of effective methods used for rehabilita-on.

The origin of the pain and disturbed function es in the involvement of various cervical nerve ots, the spinal accessory nerve and the cervical utonomic nerve, including the vertebral nerve, and the transient obstruction or compression of the ertebral artery.

he Role of Cervical Nerve Roots in Producing Pain and Headache

A major portion of the headaches associated with is syndrome are derived from traction injury to he second cervical nerve root. The second cervical nerve root is especially vulnerable to injury, since, in its peculiar anatomy, it is not protected by pedicles and facets,[2] as are all the other nerve roots in the vertebral spine (fig. 1); in addition, the point of exit of the second cervical nerve is between the atlas and the axis—the point of greatest rotation of the head on the neck.[3]

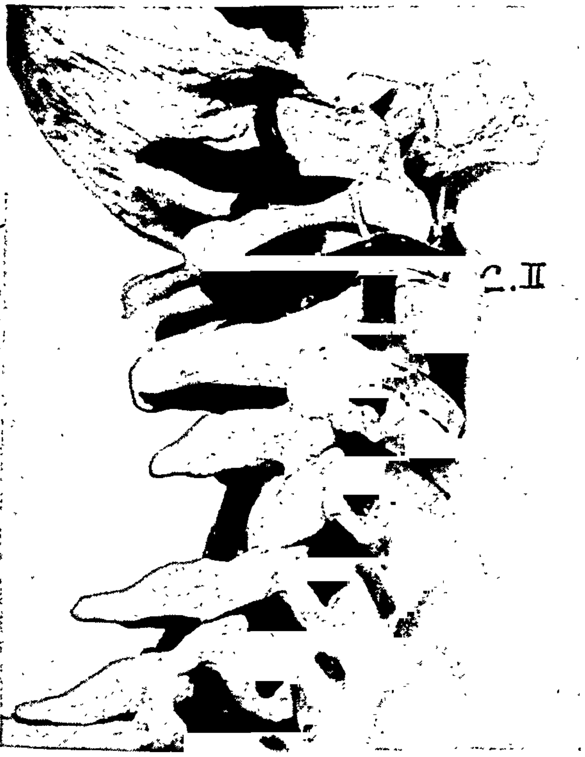

Fig. 1.—Second cervical nerve root, not protected posteriorly by pedicles and facets.

It will be remembered that the second cervical nerve continues as the great occipital nerve, which supplies the cutaneous distribution to the major portion of the scalp, the side of the neck, and portions of the face (fig. 2). In addition, the physiological communication between the second cervical and the trigeminal nerves in the spinal fifth tract of the medulla (fig. 3) involves the first division of the trigeminal nerve and thereby gives rise to attacks of hemicrania with pain radiating behind the corresponding eye.[4] This is the mechanism whereby a great many chronic and persistent headaches have their true origin in injury to the second cervical nerve, and, as I emphasized in a recent communication, "Many headaches are not headaches at all, but really a pain in the neck."[4A]

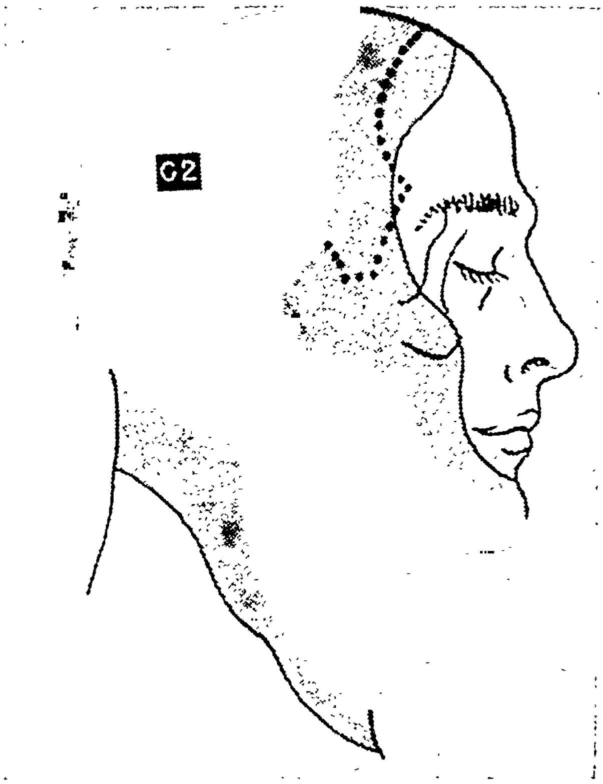

Fig. 2.—Cutaneous distribution of C-2 (reproduced with permission of Williams & Wilkins Company).

The disturbance of the great occipital nerve (C-2) is further aggravated by spasm of the trapezius muscle, since traction is thereby exerted on the nerve as it pierces the tendinous attachment of the muscle to the base of the skull.

Persistent Muscle Spasm

As previously recorded,[1] in reviewing the anatomy of the spinal accessory nerve, its major origin is by filaments from the entire length of the cervical spinal cord. From its origin, the nerve ascends through the foramen magnum and leaves the skull through the jugular foramen for a long descent to the trapezius muscle (fig. 4). The persistent spasm of the trapezius and sternomastoid muscles is due, therefore, not to primary injury to the muscles but to traction injury to the delicate filaments of origin of the spinal accessory nerve.

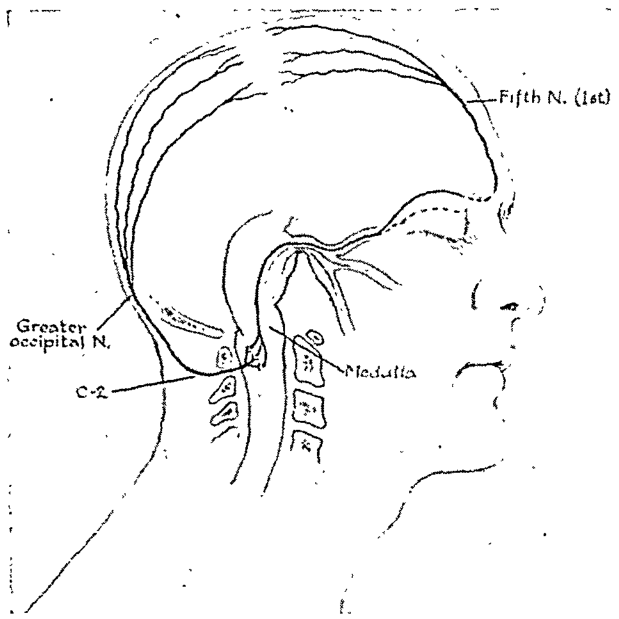

Fig. 3.—Synapse between the great occipital and trigeminal nerves (modified from Skillern[4]).

Nerve Root Irritation in the Intervertebral *Foramina*

A number of physicians have come to dislike the phrase "whiplash injury" and are critical of its use. One of my orthopedic friends calls "whiplash injury" a "wastebasket term." To him I say: "Please remove the term from your wastebasket to a place of prominence on your mahogany desk." Let us now, therefore, consider the mechanics of injury and justify the use of the terminology.

J. T. McLaughlin has shown that when a 3,500-lb. car traveling at 10 m.p.h. strikes the rear of another car it may transmit to this car a force of 25 tons. The person's body (in the car that is struck) continues to move forward, while the head, being hinged at the neck, snaps backward. The average head weighs about 8 lb., and the cervical vertebrae are very delicate; the force that is pushing the head backward is even greater than believed, since the base of the neck acts as a fulcrum and the leverage is applied near the top of the head. Therefore, the head snaps back with the equivalent of several tons of force—without any support, since "the muscular control of the neck is caught off guard."[3] The end-result, with the neck in acute hyperextension, is a momentary posterior subluxation of the various joints with fleeting narrowing of the foramina, so that the nerve root is caught in a pinchers between the superior and inferior facets.

The head now snaps back in acute flexion—a true "whip-snap" (Mark Twain's Tom Sawyer and Huck Finn used this method in killing snakes and referred to it as the whip-snap). X-rays after this type of injury usually reveal no evidence of disturbed ment, but what about the traumatized Careful neurological testing soon after the injury veals not pain but hypalgesia or anesthesia distribution *of one or more* nerves, since the ne is temporarily put out of function by the The pain and muscle spasm appear later, with ginning recovery of nerve function. During hemorrhage within the capsular ligaments giv to swelling of the nerves and eventually between the dural sleeve and the nerve root; factors give rise to symptoms that may b longed for months or even years after the

Other nerves involved are the spinal already mentioned, the sympathetic trunk, vertebral. The vertebral nerve lies within the verse foramina and travels alongside the artery. The vertebral nerve originates stellate ganglion and supplies the vertebral ilar vessels. Injury to this nerve produces the vertebral arteries and gives rise to circulation to the pons and portions of the containing the nuclei of origin of the lower cranial nerves, with resultant far-flung sym

Foraminal Encroachment

While the acute *symptoms* depend on the and severity of injury, the late symptoms are determined by the peculiarly individual of the cervical spine.[5] The cervical vertebrae course, proportionately smaller than those in parts of the spine. In addition, the disk porti even smaller in their relative sizes, because on side the space is occupied by special synovial

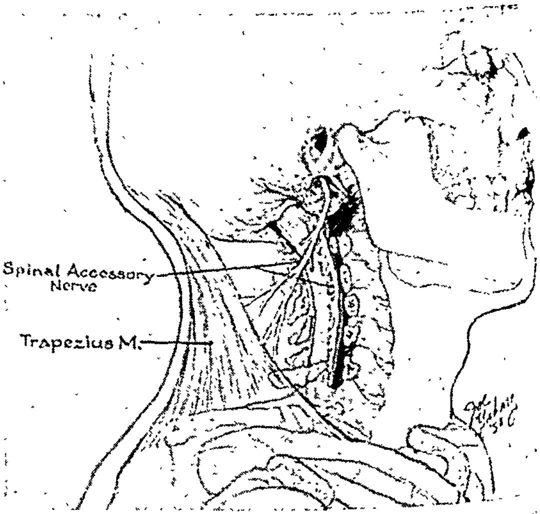

Fig. 4.—Spinal accessory nerve, with origin on ent length of cervical spinal cord. After entering skull, ner exits through jugular foramen for long descent to trapez muscles.

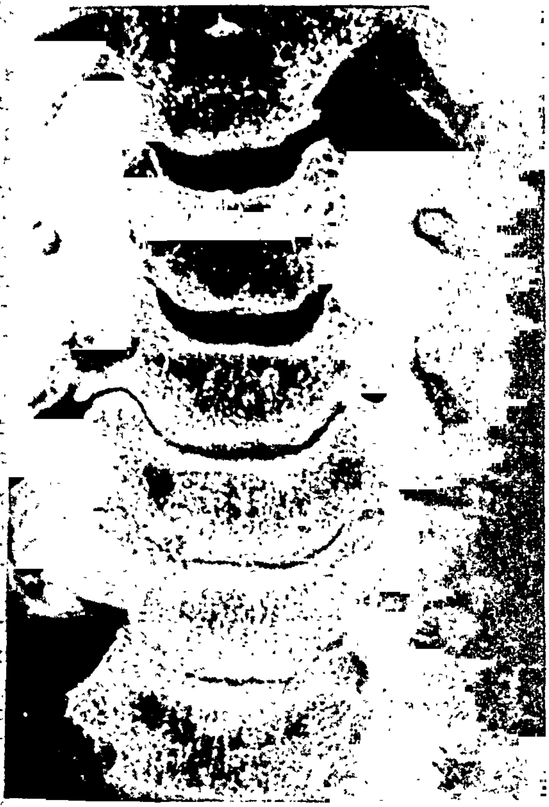
not present in other parts of the spine.[6] Althou described in 1858 by von Luschka, they are rar given proper attention because of their misleadi diminutive proportion, but the role played by the is most significant.

ith degenerative thinning of the disk after trau- he processes of the lateral joints are gradually d outward and laterally, resulting in osteophyte ation (fig. 5).

hen the spurs project laterally, they compress ntervertebral nerve root in the foramen; when project forward, they encroach on the verte-



ig. 5.—Osteophytes, resulting from degenerative thinning isk after trauma, with lateral joints forced outward (re- luced with permission of Charles C Thomas, Publisher).

l artery and nerve[7] within the foramen trans-sarium (fig. 6). These spurs project even more, ce the osteophytes are capped with cartilage l are considerably larger than is revealed by the ntgenogram.[8]

t will further be remembered that, while the cervi- foramina appear relatively large on the x-ray ture, they are partitioned by the structures not ible by x-ray, passing through the foramen trans-rsarium, namely, the vertebral artery, veins, and rve. When the gross specimen of the cervical ne is viewed obliquely, with the vertebral artery place, it is seen that three-fourths of the lateral meters of the foramina are occupied by these uctures.

Vertebral Artery Compression

In reviewing the anatomy of the vertebral artery, will be remembered that, after its origin from the bclavian artery, it passes through the foramina ansversaria of the lower six cervical transverse ocesses. After passing through the foramen trans-rsarium of the atlas, the artery turns very sharply medially and, after piercing the thick membrane between the atlas and the occipital bone, enters the cranial cavity through the formen magnum.

Very little slack exists in the vertebral artery (fig. 7), and, during severe hyperextension and hyperflexion and especially during extreme lateral rotation, partial to complete obstruction of the vertebral artery has been demonstrated by arteriography. The vertebral artery is the pipeline carrying blood and oxygen to the brain stem, just as is the oxygen tube to the deep-sea diver.

Lewis and Coburn[9] have demonstrated by angiography constriction or occlusion of the vertebral artery in patients in whom symptoms of vertigo, ataxia, headache, diplopia, and unsteadiness of gait have persisted. The usual site of occlusion is at the second cervical level, which is the point of greatest rotation of the head on the neck.

Ford[10] describes the case of a 17-year-old boy who developed attacks of syncope followed by vertigo, unsteadiness, nystagmus, and diplopia when his head was placed in hyperextension. It was determined in this case that posterior displacement of the axis, due to excessive mobility of the second cervical spine, would produce transient obstruction to the vertebral artery. Surgical fusion and mobilization gave complete cure.

Others have observed complete obstruction in the vertebral artery during angiography in cadavers when the head is rotated to either the right or the left. A great majority of symptoms that have been designated as psychoneurotic, namely, attacks of vertigo, ataxia, diplopia, severe attacks of migraine-like headache, hemicrania with nausea and vomiting, and, at times, disturbance of speech and swallowing, are all due to disturbed circulation of the vertebral artery after neck sprain.

Treatment

Physical therapy originated in antiquity and was certainly highly specialized during the inception of the Olympic games in the Hellenic Era. There are many ancient Greek statues and friezes depicting the physiotherapy measures being administered to athletes.

Circulation in the major blood vessels is propelled by the force of the pump (the heart). Circulation in the capillaries and the lymph channels within the body tissues depends on normal muscle tone and the intrinsic vasomotor homeostasis.

If the blood vessel wall has been traumatized during the injury or the vertebral nerve has been injured, vasospasm persists. The only true, effective measures for tiding over this stage of injury lie in adequate physical therapy.

Treatment must be started early and must be administered by those expertly trained in physical therapy and rehabilitation. The attempt is often made to give physical therapy in a doctor's office, consisting in the application of heat from a heat lamp or diathermy machine, as described by Krusen and Ford[11]: Those patients not receiving adequate therapy will not improve and will soon become discouraged and resentful.

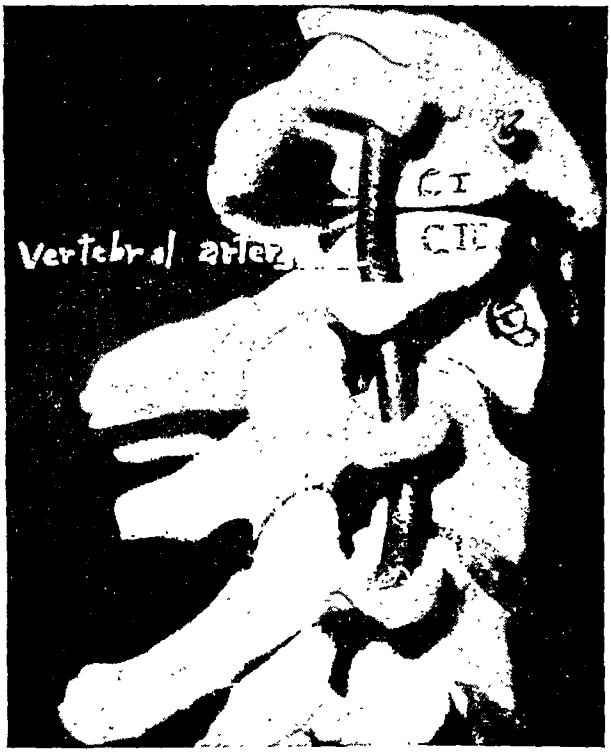

Fig. 7.—Vertebral artery.

Because of continued complaints, many of these patients finally see a psychiatrist. The couch would serve a better purpose in this instance if it were equipped with a traction apparatus and supplemented by a gentle massage. The fault, however, is not with the psychiatrist but with the referring physician. In reviewing the types of treatment with a number of specialists in this field, it is found that, while therapy naturally varies to suit the individual need, it consists primarily of local heat in the form of hot wet packs and cervical traction, followed by very gentle massage and manual rotation. When the radicular pain is severe, occasionally a local anesthetic should be injected to the most painful area, usually at the point of attachment of the trapezius muscle to the base of the skull and including the adjacent region where the great occipital nerve reaches the subcutaneous tissue.

Local hot packs relieve the muscle spasm, increase the circulation, and frequently stop severe occipital pain and headaches. The importance of a carefully planned scheme of treatment must b emphasized to the patient, and treatments must b religiously carried out daily during the first tw or three weeks (and then about three times weekly depending, of course, on the individual case. Dela or faulty treatment leads to adhesions about th facets and scarring about the capsular ligament persistent spasm, congestive lymph edema, an fibrosis of muscles, swelling, and eventual adhesion of nerves within the nerve root canals.

The resultant faulty posture in neglected case enhances the degeneration of the intervertebr disks, as well as spur formation in the lateral c vertebral articulations, which in the roentgenogra has come to be known as traumatic arthritis. I ca not too strongly emphasize the urgency of ear and persistent therapy, always by a specialist this field. By reviewing the anatomy of the cervic vertebrae and its articulations it can more readi be appreciated how injurious faulty traction traction applied by the patient can be. Jacks says, "Woe unto the doctor who hands the patie the traction apparatus and tells him to go hon and get in it."[6]

Traction serves many functions. It relieves mu cle spasm, helps to immobilize the spine, straighte the cervical spine, and enlarges the intervertebr foramina. Especially, I wish to emphasize the in portance of traction in helping to relieve obstru tion to the course of the vertebral arteries. Jackso believes that early and adequate traction may pr vent the formation of adhesions between the dur sleeve of the nerve roots and the adjacent stru tures. She has also found most valuable the u of the contour pillow, which gives excellent suppo to the neck structures during rest and sleep.

In severe spasms of the cervical spine, a ligh weight collar which maintains the neck in prop position, "with chin tucked in" and avoidance hyperextension, may be used. (Faulty postu traumatizes the cartilaginous surfaces.) Judicio use of muscle-relaxant drugs is beneficial to son patients. I personally resent the extensive use the so-called tranquilizing drugs in this type case, the sole purpose of which is to confuse th mind so that the patient will not complain.

Occasionally, a patient is seen with persiste complaints of head, neck, and shoulder pain, wh in spite of normal findings on opaque myelograph has had on surgical exposure persistent swellin and adhesions of several nerve roots within th dural sleeve of exit. It is most likely that earl persistent, and adequate therapy by those expertly trained in physical medicine will prevent most patients from developing a surgical condition.

ETIOLOGICAL FACTORS IN FIRST-DEGREE MURDER

Glen M. Duncan, M.D., Shervert H. Frazier, M.D., Edward M. Litin, M.D.,
Adelaide M. Johnson, M.D., Rochester, Minn.
and
Alfred J. Barron, M.A., St. Paul

Among six prisoners convicted of first-degree murder, remorseless physical brutality at the hands of the parents had been a constant experience for four of them. The most striking aspect of the interviews with the parents was the remarkable aptitude of these persons for evasive shifting of blame. This was followed by transparent evasions and calculated lying manifested by most of the parents. Factors of brutality come under the scrutiny of pediatricians and family physicians. Direct inquiry into the mode of punishment and discipline should be made by physicians whose practice includes the care of children. Intervention by physicians in known sadistic family patterns may well avert a later violent crime.

Murder is a tragic phenomenon. Sociologists, criminologists, jurists, dramatists, and novelists have studied it widely. To the present, little has been known of the causation of lone murder (unrelated to murder committed by gangs). The question arose in our minds as to how this problem could be approached and the causation defined. Since capital punishment is the law in the United States in all but seven states, removal of the person charged with murder presents an obvious difficulty to long-term investigation, but we were fortunate in working in a state in which there is no capital punishment. A pilot study of the problem was set up.

Fifteen years ago the collaborative technique in therapy and research in neurosis, psychosis, perversion, and delinquency first established itself as a tool for investigation. This technique consists of equally intensive studies of the patient as well as the parents and other significant relatives of the patient. Pooling of the information thus gained enables investigators to validate omissions, distortions, and falsehoods and suggests fields or avenues for further inquiry. Such studies may range from exploratory interviews to long-term analytic study of the unconscious. It is now established that, in cases of individual delinquency in children from so-called good families of all economic classes, the parents unconsciously foster and promote this behavior as a solution to their own unintegrated pathological needs. Similarly, there are adolescents whom we have studied who commit serious crimes, such as murder or sexual assault, and who also reveal a history of unwitting parental fostering of the offense. Timely interven-

---

From the Section of Psychiatry, Mayo Clinic and Foundation (Drs. Duncan, Frazier, and Litin), and the University of Minnesota (Dr. Johnson). Dr. Barron is a psychologist.

Read before the meeting of the American Orthopsychiatric Association, New York, March 6-8, 1958.

tion by pediatricians and general practitioners aware of such mechanisms has been of great value to the child and family. Wider knowledge of family patterns which predispose to adult murder might well be lifesaving.

Aim of Present Study

With the collaborative technique as a mode of inquiry, this project was devised as a pilot study to search for possible common factors in the life stories of a number of adult persons convicted of first-degree murder and imprisoned for life at the Minnesota State Prison at Stillwater. There is no capital punishment in this state. The study was made possible by the understanding and cooperation of the warden, Mr. Douglas C. Rigg, and his staff, to whom our grateful thanks are due. Since the terms of our study required that special attention be focused on the attitudes and behavior of the parents of these persons, only those prisoners whose parents were available for interview were included in the study.

Since our aim was to explore solely the possible causes of homicide, we did not concern ourselves with the questions of management, treatment, or punishment of the convicted person. This contentious field of forensic psychiatry was not entered. However, it was hoped that material would emerge in the pilot project which could be further validated by study in other states without capital punishment and which might assist criminologists in prophylaxis against murder and against the continuance of a family pattern which predisposes to such criminal violence.

We emphasize that no study was made of murderers associated with gangs or of those to whom crimes of violence were part of the cultural way of life. We believe that such offenses are sociologically determined and are more or less predictable and that prevention is largely a broad social problem. It was with the individual, isolated murderer, with no record of violent crime, that this study was concerned.

Criteria for Selection

The investigating procedure was as follows: Prisoners were selected according to certain criteria; namely, they were to be normally intelligent white men convicted of first-degree (premeditated) murder, who did not deny the crime and who were of middle-class background from families of good social standing. There should have been no history of addiction to drugs, alcoholism, organic disease of the brain, or epilepsy. There must have been no known history of psychosis prior to the murder. Both parents were to be available for interviews.

It should be noted that this was a preliminary study not involving extensive investigation of the parents' or prisoners' unconscious. It is to be hoped that this study will be followed by a more intensive collaborative investigation of the conscious and unconscious mental processes of prisoners and their parents.

In each instance it was made quite clear that the psychiatrists were in no way connected with the prison management, the courts, or the legislature. Participation of a prisoner would not influence his treatment or sentence in any way whatever. The prison psychologist, whom they trusted, explained the investigation to the subjects in advance and also introduced the psychiatrist to the subjects in each case. No information which the prisoner or relative wished to have maintained confidential was disclosed to anyone outside the research team. Parents and prisoners were told that their cooperation would help the investigators learn something which might be of service in the prevention of tragedies similar to their own. Of course, interviews were conducted in private.

In view of these provisions, there was minimal temptation to distort material in order to protect the prisoner or to modify his sentence. Only by such procedures could meaningful data be gathered and some measure of truth ascertained. Aside from important biographical facts, special attention was paid to the feelings and attitudes of each person interviewed and to understanding what contribution these might have made to the eventual crime. The psychiatrists were thus alerted to any attitude or manner of the parents which might have allowed their child to sense that a violent solution to disputes with others was an acceptable thing.

When six subjects had been selected, interviews were arranged with them and with their parents. In interviews with prisoners, the first striking impression was the readiness with which they discussed the crime and the events leading up to it. They also invited return interviews, although they knew that no legal advantages would accrue to them as a result of additional consultations. They did not try to escape responsibility for the crime or to lay the blame on others. Almost without exception, when the stories of prisoner and family were at variance the prisoner was found to be telling the truth. We wish to acknowledge our indebtedness to the prisoners and to their families for their ready cooperation and willingness to participate in the interviews.

These studies led to the conclusion that, among these prisoners, remorseless physical brutality at the hands of the parents had been a constant experience. Brutality far beyond the ordinary excuses of discipline had been perpetrated on them; often, it was so extreme as to compel neighbors to intercede for the boy. In no case was any effort made by the prisoner to conceal the crime or to evade capture.

The most striking aspect of the interviews with the parents was the remarkable aptitude of these persons for evasive shifting of blame. Nor was there any suggestion from them of self-criticism or guilt over their sons' upbringing or downfall. They repeatedly and steadfastly lied on many important matters of fact, often differing sharply from their spouses or offspring, and often they remained unshaken by glaring discrepancies.

We shall present reports of two of the six cases.

Report of Cases

CASE 1.—In a jealous rage, a 30-year-old man found an ax and, in the presence of neighbors, killed his former sweetheart. Originally, he had seduced her away from his brother when the latter went to Europe on military duty.

This man, the second of six children, had been the target for the most violent uncontrolled brutality on the part of the father, who, although he had a good job as a shop foreman, was a philandering alcoholic and a physical and mental sadist in his relationships with the prisoner's mother. The father's wild beatings of the boy were so frightening that neighbor men often interceded. The mother said she continued to live with the father only "to be sure he did not kill one of the boys," while at the same time her husband doted on the older daughter, of whom the prisoner was violently jealous. The father often beat and choked the mother in the children's presence. He shouted that she was a whore and that he would kill her some day. From the time the boy was 3 years old, the mother said, he recurrently ran away from home because he was so terrified of the father. From the time the boy was 14 years old, his father accused him of vicious sexual practices with girls, a charge which was not true at the time. The mother said that the father constantly "spoke evilly about other people's sex lives" in the presence of the children. At no time did the father ever accept any responsibility for his brutal acts, and he never expressed any remorse. The boy never dared to bring a young friend into the home.

The mother offered no protection to the child against the father's attacks, but she did console him afterward. She never called the police to protect the boy. She and the prisoner leaned on each other emotionally, and apparently he was always tender with her. At no time did the mother express any guilt or responsibility for having kept the boy in such a savage environment, and at the time we saw her the next oldest son was experiencing a similar life with the father. The prisoner said that without her warmth and comfort he would have killed himself long ago. He cried and moaned about his love for her for 15 minutes when she was first mentioned in the interview. He could not recall any conscious hostility toward his mother.

He always felt that his fiancée was better than he and above him socially. He made no protests when she had promiscuous affairs with others and left him. Later, for a time, he tried to win her back, after she had married. However, he began to live with a woman 10 years his senior, an occurrence which prompted his former fiancée to divorce her husband and to attempt to woo him back, promising marriage. As a result of this, he abandoned the woman with whom he had been living, whereupon the former fiancée began to go out with other men. The prisoner found an ax and killed her.

Several facts stand out in this case. First, the patient had strongly identified with his father. He saw how sadistic his father was toward the mother as well as toward himself. Although consciously he loved his mother, he hated her unconsciously for not protecting him from the years of savage attacks. Similarly, she seduced him with consolations after the assaults and sought his sympathy as years went on and her plight continued. The prisoner stole his brother's girl, felt she was above him, and then for a brief time consoled himself with an older companion. Finally, the savagery he had felt and learned at the hands of his father came out toward the alternately unfaithful and seductive fiancée. She was merely repeating the lifelong behavior of his mother, who alternately abandoned him to this father's brutality and then wooed him back with sentimental consolation.

His mother said that the father made no secret of his violent attacks on her sexually, verbally, and physically and that the sons knew all about these attacks. It was only by a stroke of luck that this prisoner actually was not killed by his father. The mother had always feared it and believed the father capable of it. The prisoner had known of his mother's fear for years. This boy, by direct example, learned that frustration and anger were to be handled by violence. He learned that men are brutal to women. The tremendous unconscious hatred for his mother, who submitted to the father and then turned to the prisoner for love, finally overwhelmed him at the expense of his alternately promiscuous and seductive fiancée.

CASE 2.—This prisoner was 27 years old when he strangled his sweetheart. When we saw him he was unable to account for his killing her. "Those 12 months with her—I wouldn't trade them even to being in this prison for life." He murdered her when she refused to marry him.

He said he wondered if he had not "misidentified" his victim with her interfering mother, of whom he said in all seriousness he would "gladly wring her neck." He also remarked, "If it hadn't been Rosie I killed, it would have been someone else—it was inevitable."

He was exceedingly bitter toward his own mother. "Mom hated me since the day I was conceived. I was an unfortunate burden on her. It wasn't my fault I was born. She has punished me ever since, though, for it. I can remember all the unmerciful beatings she gave me. She is happy now that she has completely destroyed my life."

He said she was vicious; she would choke him and beat him so hard with a barrel stave that he became bruised and bleeding. She used to say to him: "What did I ever do that God thinks I deserved to have you wished on me!"

His mother constantly belittled his father, and, whenever the father protested these humiliations, she threatened him with the "disgrace" of separation. "She destroyed any standing he might have had in my eyes," said the prisoner.

The mother told us of how her father "ran out" on the family when she was 5 years old, and she said he never supported them (a pattern her son repeated in the action of causing two unmarried girls to become pregnant and then abandoning them). Throughout her childhood the mother had been accused by other children of being illegitimate. No mention was allowed of the father by the family, and she had never heard other mention of him until she was 10 years old. It is clear how this hostility toward her father had carried over toward the son.

She reported that "the whole idea of John was a big mistake." She added that she had been angry about the pregnancy, blaming her husband's carelessness. She readily confirmed to us her son's account of her cruel and unusual punishment of him. It was remarkable to the interviewer how devoid she was of any sense of guilt about her rejection and cruelty. She explicitly said of his tantrums and ungovernable rages that "he acted how I felt." Local feeling in the community had been against the boy from the age of 5 years because of his violent temper, and from the age of 7 years he had been wrongly but persistently accused, over many years, of pushing a young companion to his death from a roof.

"His whole childhood was filled with anger," said the mother. She said she always thought he would get into trouble. "He grew up thinking the same way. He felt everyone was against him." At the time we saw her, she said she was glad the son was in prison and she hoped the authorities would never release him.

In this instance we have ample evidence for the prisoner's modeling himself after his vindictive and remorseless mother. She made it clear that the behavior of the son was in accord with her feelings. Satisfactory identification by the boy with his acquiescent, unprotecting father was not possible. The only close friend the boy had was an orphan boy older than himself who had lived with the family for a short while. As a boy, the prisoner often would stay away from school to dig worms for, and to go fishing with, a group of older men, who made much of him. His mother was aware of his truancy with these older men.

In the later life of this prisoner it seems that the mother of his sweetheart was the nominal target for his hostility, but when the girl herself spurned him he had no compunction about turning his vengeance on her. His lack of sense of guilt or restraint was modeled after those defects in his mother.

Comment

The most striking common feature in four of the six cases was the continuous, remorseless brutality which the prisoners in question had suffered at the hands of one parent, in the face of the compliant acquiescence of the other.

We discovered evidence in the case of the remaining two that the prisoners were psychotic at the time of the murder, and, of these, one was clinically psychotic during the study. In these two cases there was no history of gross brutality.

An example of the level of the brutality in the four cases was an incident in which the father held up his nude little boy by the heels, belted him, then dropped him on his head to the floor. Recurrently, some prisoners, when children, had been flung bodily across a room. Only by chance were some of them not fatally injured. Although such violence was a common factor in the four cases, it should not be concluded from them that violence is the major factor in the etiology of murder. This, at present, we cannot say. Imitation and identification with violent parents, however, constituted the commonest pattern found.

Another impressive feature was the absence of a sense of guilt on the part of the parents, yet, when the circumstances of their own upbringing became clear, the source of their hostility and of their lack of remorse was obvious. The interviewers were startled by some of the transparent evasions and calculated lying manifested by most of the parents. Yet, in contrast, the prisoners were found, by investigation, to be giving true accounts of events. The probable reason for such a situation was that the prisoners had nothing to lose by telling the truth, whereas the parents were still trying to absolve themselves from any responsibility for the tragedy. This observation confirmed findings long known to prison authorities, namely, that prisoners are most cooperative when given the opportunity to be so.

Still another interesting observation was the fact that these psychiatrically unsophisticated prisoners showed a surprising degree of insight in relating their criminal violence to their family experiences. Furthermore, documented evidence showed that no prisoner had attempted to escape from the scene of the crime and that none had denied committing the offense. All defended their actions, but none disputed the fact of the killing or of the premeditation.

Of interest to psychiatrists was the constant finding of deep, unconscious homosexual tendencies, a finding which is not surprising in view of the brutality disclosed. Often these tendencies were revealed in frankly paranoid behavior. In three of the cases such trends were reinforced by contrasting favorable treatment of a sister.

In contradistinction to previous experience with individual juvenile delinquents and adolescents guilty of serious crime in whom unconscious parental fostering was a powerful factor driving the child toward acting-out, these adult persons, convicted of first-degree murder, revealed a minimum of unconscious parental fostering. Instead, the acts of violence seemed to be much more on a conscious imitative level, reflecting actual childhood experience.

An interesting aspect of the investigation was the consistent pattern of behavior and personality of the victims. Female victims were by turns seductive and rejecting; male victims were threatening figures who carried weapons.

It seems to the investigators that factors of brutality such as have been outlined above must come under the scrutiny of pediatricians and family physicians. Direct inquiry into the mode of punishment and discipline should be made by physicians whose practice includes the care of children. It is felt that intervention by them in known sadistic family patterns may well avert a later violent crime.

Clearly, since the studies here reported are preliminary and not satistically valid, additional extensive and intensive work must be done with similar subjects. To this end, work is already under way by us with teen-age first-degree murderers.

Summary

Six prisoners convicted of first-degree murder and their parents consented to undergo investigation by the collaborative technique in a pilot study. White male prisoners were selected who were of at least average intelligence, from middle-class families, not members of a gang, not alcoholic or epileptic, and with neither organic disease of the brain nor a history of psychosis.

Remorseless physical brutality inflicted through the childhood and adolescence of the prisoner at the hands of parents was a common factor in four cases. The other two prisoners proved to have been psychotic at the time of the murder, and these two had not been treated with such gross brutality.

Unconscious fostering by parents, such as has been described frequently in individual delinquency, was not observed in these cases. Rather, the prisoners learned to behave like their brutal aggressors and learned by conscious example that violence was a solution to frustration.

The need for family physicians and pediatricians to be aware of, and to intervene in, such brutal family patterns is emphasized with a view to preventing possible tragedy.

JEJUNAL INTERPOSITION OPERATION—ANALYSIS OF THIRTY-THREE CLINICAL CASES

George I. Thomas, M.D.
and
K. Alvin Merendino, M.D., Seattle

It is now possible to excise the esophagogastric junction for such conditions as reflux esophagitis with stricture with restoration of continuity and without fear of recurrent esophagitis. The operation here described involves the interposition of a segment of jejunum, from 15 to 48 cm. in length, with certain precautions taken to make sure of a good blood supply. Four anastomoses have to be made, the most crucial being that between the esophagus and the jejunal segment. In a period of six years this interposition operation has been carried out in 33 patients. Four postoperative deaths occurred, and analysis of the case histories indicates that improvements in technique would reduce the mortality significantly. Among the other 29 patients there has been no dysphagia, and the functioning of the interposed segment of jejunum has been studied by roentgen ray in patients up to six years after operation. All patients, including some with cardiospasm, esophageal varices, and lye stricture, were relieved to be able to swallow normally again, and the majority ate three meals a day, but 6 established a pattern of eating five or six times a day, and 12 were apparently unable to vomit. The substitution of a segment of jejunum for the esophagogastric sphincter is a sound physiological procedure.

In 1955, the concept of cardioesophageal sphincter substitution by the interposition of a segment of jejunum between the esophagus and the stomach was presented.[1] Included in this publication were case reports of patients in whom this operation had been performed for various lesions, mainly of the lower part of the esophagus. Since then, additional clinical experience has served to strengthen the validity of this concept.

Previous publications from this laboratory have documented the experimental background for this procedure.[2] From this work the following facts have evolved: The mucosa of the interposed jejunal segment in its new position exhibits a greater resistance to acid-peptic digestion than the mucosa of either the stomach or duodenum. By its peristaltic activity, the interposed jejunal segment prevents the regurgitation of peptic juices into the esophagus and, thus, protects the esophagus from esophagitis. Jejunitis is likewise prevented by this peristaltic action, and the isoperistaltic jejunum provides a satisfactory conduit for the passage of food into the stomach.

Consequently, the jejunal interposition operation has been utilized for a number of conditions wherein it is necessary to incise or excise the esophagogastric junction. Most frequently, it has been used in reflux esophagitis with stricture in the presence of a traction type of hiatus hernia, but the procedure has also been performed in patients with stenosing esophagitis without demonstrable hernia. In addition, the "interposition" operation has been used in patients with cardiospasm. In both situations, the need is for a new sphincteric mechanism, in one instance because of incompetency and in the other because of spasm. Patients with life-endangering esophageal varices of the extrahepatic portal bed block type, after failure of previous surgical therapy, have constituted another small group in which this operation has been utilized. In the latter situation, the philosophy of this approach is based on the assumption that massive bleeding from esophageal varices may be precipitated by reflux esophagitis and that the varices may in themselves prevent competency of the sphincter. The remaining conditions for which the operation has been used may be classified as miscellaneous, e.g., lye stricture, where there is need mainly for esophageal substitution, but for sphincteric substitution as well. No operations have been performed for histologically malignant disease, although certain of the lesions encountered may have resulted in the eventual death of the patient if the disease had been untreated.

It is the purpose of this paper to analyze the early experience with and follow-up data of 33 patients who have been subjected to the jejunal interposition operation and to describe briefly certain surgical details which, with increased experience, appear to be important.

From the Department of Surgery, University of Washington School of Medicine.

Read before the Section on Surgery, General and Abdominal, at the 107th Annual Meeting of the American Medical Association, San Francisco, June 27, 1958.

Operative Procedure

The major details of the operative procedure have been described previously[1] (fig. 1). Briefly, the patient is placed in the supine position with the left side slightly elevated at a 20-to-25-degree angle.

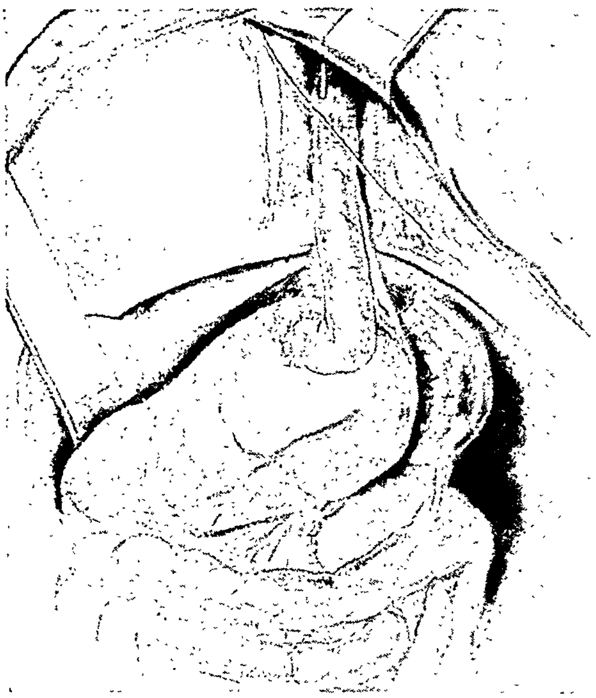

Fig. 1.—Completed jejunal interposition operation, including bilateral vagotomy and Finney's pyloroplasty. Note preservation of left phrenic nerve.

A supraumbilical midline incision is extended into the left lateral portion of the chest through the fifth or sixth intercostal space. In dividing the diaphragm, it is important to avoid severance of the phrenic nerve. Care is taken to identify the phrenic nerve within the pericardiophrenic fat pad. Once the nerve is isolated, the diaphragmatic incision is carried out medial to the main nerve trunk and lateral to the pericardial attachment with the diaphragm down to the esophageal hiatus. This effects only division of the left sternal branch of the phrenic nerve, thus denervating only a small anterior segment of diaphragmatic musculature and avoiding any major loss of pulmonary function.[3] Furthermore, one should avoid overstretching the main phrenic nerve within its sheath. Therefore, it is important to dissect the nerve from the pericardium to a point high enough to avoid overstretching of the nerve when the chest cage is retracted for exposure.

After the esophagus and a small portion of cardia ventriculi have been excised, two main details in the selection and preparation of the jejunum demand attention. The first is the selection of the major jejunal artery which will supply the segment. The first or second jejunal arteries distal to the ligament of Treitz are short and generally not used. The third or fourth jejunal arteries generally run independent of the major vein and are frequently chosen to supply the proximal segment. Here one must check the branches of the primary arcades to be sure that the junction between the intestinal arcades is adequate (fig. 2).

While attention has been drawn to the arterial patterns, the venous patterns, particularly of the major veins, are of equal importance. Ordinarily, the smaller veins parallel the arterial channels; however, the main venous trunks draining the segment may be spatially separated from the arterial trunk and must be divided with care separately. It is well to remember that the arteries, being thick-walled with high intraluminal pressure, will bend like a sapling where some pressure point exists on the segment. On the other hand, the veins, being thin-walled with low intraluminal pressure, may kink. Consequently, to avoid difficulty, a second detail of importance is to leave intact a border of mesentery along the cut edge of the segment which parallels the main vessels of the pedicle. This effects a protective zone to the vulnerable vein which may be twisted or injured. Additional length of the segment should not be attempted by stripping the vessels free of the leaves of the mesentery. It seems better to utilize a lower jejunal artery which affords a gain of from 5 to 15 cm. of jejunum. Terminal branches or collecting tubules of the jejunal arteries are direct branches of the primary arcades, which simplifies the decision as to the site of proximal division of the mesentery close to the intestine.

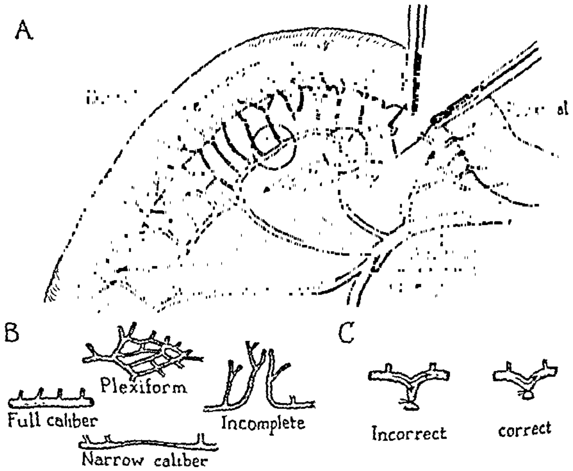

Fig. 2.—A, schematic drawing of upper jejunum, showing division and mesenteric route of dissection in order to utilize third or fourth jejunal artery for jejunal segments vascular pedicle. B, four types of arcuate (primary) connections commonly found between major jejunal arteries. C, correct method of ligating distal jejunal stump, avoiding loss of dissipation or pulse pressure to segment.

The jejunal segment is passed through an aperture in the avascular portion of the transverse mesocolon, posterior to the gastric fundus, and elevated to the divided proximal esophagus. A careful check now should be made to be certain that the pedicle is free from rotation, kinking, or pressure. It should lie loose and easily in the open hiatus, without tension on its vasculature. The various anastomoses are carried out in a standard fashion and need no additional comment.

In this series, the length varies from 15 to 48 cm., depending on body build, amount of esophagus resected, and anatomic arrangement of the jejunal vasculature. However, it is important that any excess jejunum lies below the diaphragm after diaphragmatic reconstruction. At this stage, it is important to suture the jejunal wall to the edge of the new diaphragmatic hiatus and condition the intraperitoneal arrangement of jejunum by an indwelling nasogastric tube in order to avoid any obstruction of the segment.

In this series of 33 patients, in the first 2 the operation was done as a two-stage procedure and in 30 as a one-stage procedure. In one patient, who had a long esophageal lye stricture, the jejunal loop was brought up in the anterior mediastinum because of technical difficulties associated with multiple previous abdominal procedures. A second-stage cervical esophagojejunal anastomosis then was performed eight weeks later. Also for technical reasons, in four patients a Heineke-Mikulicz pyloroplasty was performed instead of Finney's pyloroplasty. The latter appears to provide more adequate gastric drainage and, in our experience, is the preferable ancillary drainage procedure accompanying vagotomy.

Preliminary gastrostomy was carried out in two patients because of the need for laparotomy prior to cardioesophageal resection (complete esophageal obstruction from lye stricture in one patient and esophageal perforation in another). Postoperative gastrostomy for gastric suction has not been found necessary, since a nasogastric tube is always inserted for the purpose of conditioning the arrangement of excess jejunum below the diaphragm.

In patients with evidence of moderate weight loss, blood transfusions and high-calorie, high-protein, liquid diets (often administered through the finest of polyethylene catheters in the presence of a tight stricture) aid in the preoperative management.

Clinical Material

From Oct. 1, 1952, through March, 1958, a period of five and one-half years, 33 patients were operated on for various lesions of the esophagus or cardioesophageal sphincter. Table 1 shows in tabulated form the heterogeneous group of cases comprising this series. The predominant lesion for which the operation was performed was peptic esophagitis. In these 20 patients, varying degrees of organic stricture were common to all with associated dysphagia, substernal pain, heart burn, dietary restriction, and weight loss. Repeated dilatation had been performed in 11 of these patients. An additional five patients of this group had had previous attempts at transthoracic repair of hiatus hernia (table 1).

Seven patients with symptomatic cardiospasm were operated on, four being treated primarily by excision and jejunal interposition, and three by this procedure after previous operative measures had failed to achieve satisfactory results. The remaining six patients required cardioesophageal replacement for the following conditions: esophageal varices, lye stricture, and an operation-induced esophageal stricture which has been termed "iatrogenic" stricture. Previous major operations (excluding dilatation) in 11 patients are listed in table 1.

Table 1.—*Previous Major Operations in Eleven Patients*

	Operations, No.	Patients, No.
Peptic esophagitis with stricture		
Transthoracic hiatus hernia repair	5	5
Cardiospasm		
Cardioplasty, type unknown	1	1
Transthoracic hiatus hernia repair	1	
Gröndahl procedure	1	1
Subtotal gastrectomy (80%)	1	
Heller esophagomyotomy	1	1
Esophageal varices		
Splenectomy	1	1
Subtotal gastrectomy (75%)	1	
Portocaval anastomosis	1	
Splenectomy	1	1
Failed portocaval anastomosis	1	
Transesophageal ligation	1	
Iatrogenic stricture		
Transthoracic hiatus hernia repair	3	1
Total	19	11

The youngest patient in this series was 8 years and the oldest 75 years of age. Ten patients (33.3%) were between 60 and 75 years of age. Twenty-one patients were men, with a sex ratio of 2.2 men to 1 woman.

Immediate Results

Of the 33 patients operated on, a careful follow-up of 32 patients has been possible. Only one patient was lost to the study. This series is presented as an early experience with a new procedure, and certain difficulties have been encountered as a natural consequence of learning. Table 2 reveals all the complications encountered. In each operation, four anastomoses are performed. Thus, a total of approximately 130 anastomoses were carried out. Three suture-line leaks occurred, and all were at the esophagojejunal anastomoses. Six major electrolyte disturbances occurred and have been included under hyponatremia, symptomatic or asymptomatic. Serum sodium levels under 128 mEq. per liter were present in all six patients, with three producing such symptoms as mental torpor, confusion, lassitude, and fatigability. Two patients required interval postoperative resection of un-healed or ununited costocartilages at the junction of the thoracic and abdominal incision. These nonunions produced pain and/or unpleasant false motion of the chest and were relieved by simple excision. In one patient, a subscapular infection required partial scapulectomy and drainage. Cardiopulmonary complications have been surprisingly low, despite the somewhat advanced age of the majority of patients. Preoperative preparation, attention to details, and, especially, postoperative care of the tracheobronchial tree are most important. Tracheotomy was performed in three patients who were unable to manage excessive tracheobronchial secretions. There were four postoperative deaths (12.1%). A brief summary of each case is presented here.

Report of Cases

Case 1.—A 75-year-old woman was operated on for peptic esophagitis, ectopic gastric mucosa, and stricture on Oct. 6, 1954. Preoperative dilatation had been of no benefit. A 30-cm. jejunal segment was interposed between the esophagus, immediately below the aortic arch, and stomach combined with Finney's pyloroplasty and bilateral vagotomy. On Oct. 14, severe hypochloremic alkalosis was present with dehydration, shock, fever, left lower lobe atelectasis, and pneumonia. Despite correction of electrolyte imbalance and administration of massive doses of antibiotics, death occurred on Oct. 19, 13 days after operation.

Autopsy findings included left lower lobe atelectasis and pneumonia, mediastinitis with small abscess, and perforation of the distal part of the stomach with abscess (due to a hard, plastic tube penetrating the stomach wall), producing outlet obstruction of the stomach which abetted and perpetuated the electrolyte problem.

Since this experience, no plastic nasogastric tubes have been used in these patients.

Case 2.—A 53-year-old man, a chronic alcoholic, was operated on for peptic esophagitis with stricture and traction-type hiatus hernia on Feb. 2, 1956. A 15-cm. jejunal segment was interposed between the lower part of the esophagus and stomach with bilateral vagotomy and Finney's pyloroplasty. Fifteen hours after the operation, massive subcutaneous emphysema was present with respiratory insufficiency. Death occurred early on Feb. 7, 1956.

An autopsy permit was not obtained. It is assumed that a major tracheobronchial leak existed in the presence of an occluded thoracotomy drainage tube.

At surgery, there was obliteration of the pleural space due to visceroparietal adhesions. These were divided and the lung mobilized without evidence of air leak at that time. On the evening of surgery, subcutaneous emphysema was noted. The severity of this was not appreciated, and early the next morning extreme respiratory distress occurred. Inadequate nursing staff at this inopportune time resulted in delay of communication to the resident staff and the needless death of this patient. The obvious therapy needed was a tracheotomy and evacuation of trapped pleural air. This death was entirely preventable.

Case 3.—A 56-year-old man was operated on for peptic esophagitis with stricture and traction-type hiatus hernia on Jan. 29, 1957. A 25-cm. jejunal segment was interposed between the midesophagus and stomach at the level of the aortic arch. The procedure was prolonged due to venous infarction of the first segment replaced by a second segment; the latter anastomosis was accomplished through a second thoracotomy incision. A right-sided hemiplegia with signs of cerebral anoxia was present the next day. The gastric tube drainage became bloody, amounting to 2,500 cc. by the second postoperative day, at which time death occurred. At no time was the patient's general condition satisfactory for reexploration.

Autopsy findings included cerebral thrombosis on the left side, both old and recent, pulmonary emphysema with healed pleuritis, and venous congestion (infarct) of jejunal segment with intestinal hemorrhage due to jejunal vein damage.

This patient had had pulmonary emphysema of moderate degree, a cerebral vascular accident three months prior to operation, and treated syphilis with residual tabes dorsalis. Irrespective of the direct cause of death, he was a poor candidate for this or any other major surgical procedure, and the decision to operate represents an error in surgical judgment. The need for a second thoracotomy incision to facilitate the esophagojejunal anastomosis indicates the inadequacy of the exposure for an anastomosis directly under the aortic arch in the left thoracotomy incision in continuity with the abdominal incision. When an anastomosis must be made high under the aortic arch, separate abdominal and right thoracotomy incisions now are advocated.

Case 4.—A 53-year-old man was operated on for peptic esophagitis, stricture, and hiatus hernia on June 27, 1957. A 26-cm. jejunal segment was interposed between the midesophagus and stomach, combined with Finney's pyloroplasty and bilateral vagotomy. Inadvertently the segment was rotated 360 degrees, and the esophagojejunal anastomoses had to be taken down. A second difficult anastomosis was accomplished immediately under the aortic arch. Ineffectual coughing, atelectasis, and profuse secretions necessitated tracheotomy on the fifth postoperative day. On the seventh day, gastrointestinal bleeding occurred with evident pyopneumothorax on the right side. The patient died on July 4, 1957, despite transfusions and the insertion of a thoracotomy tube in the right pleural cavity.

Autopsy findings included mediastinal and right pleural empyema, esophagojejunal anastomotic leak with esophagopleural fistula, severe tracheobronchitis, and left lobe pneumonia.

Again, this case shows that the proximal esophagojejunal anastomosis is the most critical anastomosis to perform. The higher the resection is, the more difficult it is to secure an accurate two-layer anastomosis. As noted previously, it is now preferred to use a midline supraumbilical incision and a separate right thoracotomy incision for high infra-aortic arch anastomoses.

Table 3.—*Data in Twenty-five Patients Available for Follow-up Study After Jejunal Interposition Operation*

* Esophagoscopy done repeatedly, with no regurgitation or esophagitis demonstrated.

† Operated on for esophageal varices, extrahepatic type, with complicated course and prolonged hospitalization. During hospitalization diabetis mellitis became manifest. In addition, there have been two minor episodes of melena.

Late Results

There were three late deaths (9.1%), none of which were attributable to the jejunal interposition operation. The interval from operation to death was 6 months in a 59-year-old man,. 12 months in a 67-year-old man, and 23 months in a 72-year-old man. All three were severe chronic alcoholics; alcoholism was the direct cause of death in one patient. The cause of death in another was accidental strangulation while intoxicated, and the third died of a cerebral vascular accident. Unfortunately, no tissue was available for pathological study, due to circumstances associated with the death of each patient.

Follow-up Analysis

Table 3 is a tabulation of the critical features in each of the 25 patients (75.7%) available for follow-up study.

Weight.—There was a gratifying weight increase in 68% of the patients, ranging from 10% to a high of 43.4% over the preoperative weight. The average gain of these 17 patients was 14.1% over the preoperative weight. Eight (32%) of the series showed an average decline in weight of 6.2% (fig. 3). There appears to be no significant increase or decline when plotting the postoperative interval against percentage weight gain or weight loss. The only correlation with respect to the time interval after operation is that, in general, a stationary level was reached and then maintained within a six-month period. During this period of time, dietary readjustments occurred and a distinctive pattern of calorie intake was established. Three of the patients in the weight loss group were severe alcoholics with extremely poor dietary habits.

The majority of the patients had lost weight prior to operation; therefore, the correct or normal weight could not be adequately ascertained. None of the patients were severely debilitated or starved, and the preoperative weight used for comparison reflected the best nutritional state possible prior to the operative procedure. The over-all pattern indicates a significant metabolic improvement.

Meals.—During the first three to nine months, most of the patients experienced substernal and epigastric discomfort with ingestion of food quantities approximating a normal-size meal and, therefore, ate more frequently. After this period, the majority of patients ate three meals a day, corresponding to the normal eating habits of other members of their family. There appears to be no major restriction of any particular food, though three patients developed a definite dislike for dairy products, particularly milk. Of the entire group, six patients, all operated on over two years ago, have, at the time of writing, established a pattern of eating four to five times per day.

Swallowing.—There was no dysphagia in the entire group. All of the patients expressed delight in the ability to swallow "normally" without pain, and this is a most pleasant experience for this group of patients. Seven patients claimed that there was a delay in the swallowing mechanism. In three patients, this was a definite though minor annoyance. In one patient, x-ray showed active peristalsis of the 20-cm. jejunal segment with rapid emptying of both *jejunum and stomach. His subjective feeling* of delay is, therefore, unexplainable.

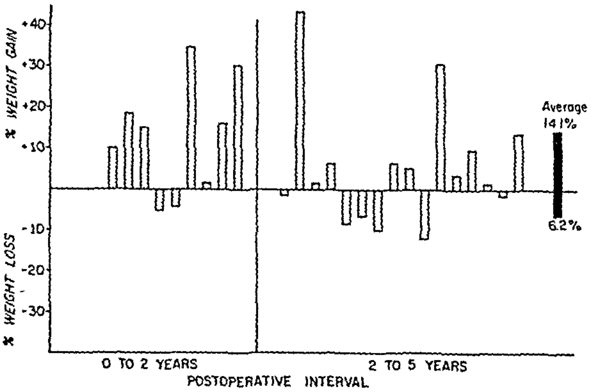

Fig. 3.—Weight gain or loss in 25 patients after operation.

Figure 4 shows a sequence of a peristaltic wave outlined by barium swallow passing through a 25-cm. jejunal segment which was interposed almost six years ago in one patient. Although peristalsis remains active in these sequestrated segments, *there can be no doubt that the passage time* of food through the jejunal segment is delayed over that of the proximal normal esophagus. Truly remarkable, however, is the high percentage (72%) of patients with subjective normal swallowing. The explanation of this essential normality in swallowing probably is the fact that the average bolus of food swallowed does not overdistend the jejunal loop. Whereas swallowing of solid material was normal in most of the patients, many noticed an inability to drink fluids rapidly, since this produces an uncomfortable sensation in the substernal or epigastric regions. This probably produces rapid distention of the jejunum, and the symptoms are related thereto.

Dumping Syndrome.—We define "dumping" as the occurrence of "sweating," unpleasant warmth, subjective flushing, weakness, palpitation, nausea, or explosive diarrhea, with the onset within 15 minutes after eating and lasting up to 45 minutes, relieved partially by lying down. Thirteen patients (52%) experienced one or more of these symptoms *in varying degrees early in the postoperative period.* In only one patient was this incapacitating. A short period of hospitalization was required for management. Late dumping was present in three patients (13.3%) and was of no major significance. Two of these patients were troubled with the dumping syndrome only after eating sugar. The *presence of Finney's pyloroplasty may account for* this. One additional patient, a severe chronic alcoholic, had frequent bouts of diarrhea, while six patients had occasional and transient episodes of diarrhea, possibly attributable to the vagotomy.

Ability to Vomit.—The question has arisen as to whether these patients can vomit. Three patients (12%) were capable of true vomiting, i. e., the regurgitation of digested or partially digested, bitter tasting, bile-stained food from the stomach. Four other patients (16%) stated that they were able to regurgitate food, phlegm, or mucus, but only in small amounts and often immediately after eating. This does not represent true vomiting, but *simply regurgitation from the esophagus or jejunal* segment.

In the remaining 18 patients, 12 (48%) were apparently unable to vomit. None felt that this is a disadvantage, and two patients expressed the opinion that there was a certain advantage in not being able to vomit. Five (20%) had no experience, and in one the information was not known. There was no correlation between the ability to vomit and the jejunal segment length or any other aspect of the surgical procedure. Experimentally, dogs with interposed jejunal segments demonstrated no anatomic lesions when sacrificed immediately after severe vomiting induced by apomorphine administration.

Alcohol Intake.—Because alcohol provokes excessive acid-peptic secretion and therefore affords a severe test for the operative procedure, we have been particularly interested in the postoperative course of the chronic alcoholics who have been subjected to jejunal interposition. Of nine patients, six are included in the follow-up group. Four were operated on over 22 months ago. One patient has had mild heartburn, particularly after drinking, but no esophagitis by esophagoscopy. The remaining three were very satisfied with their operation. The longest follow-up study in this regard was in a patient who was operated on over 69 months ago. Despite constant alcoholic ingestion and two hospitalizations for pellagra, he is completely asymptomatic. There is no doubt that vagotomy and Finney's pyloroplasty reduce the ulcerogenic response of alcohol in the stomach; needless to say, it is an unphysiological stress agent and is in the same category as the stimulation of parenterally given histamine in the test dog.[4] The overindulgence in alcohol plus the associated lack of neutralizing food in the stomach constitutes a severe test of the jejunum segment as well as the stomach and duodenum.

Comment

This study indicates that all patients have been cured of the disease for which the operation was performed. Consequently, the concept of sphincter substitution appears valid. Furthermore, any speculation concerning the ability of the jejunal segment to resist acid-peptic digestion has been negated by absence of any evidence of such pathology to date.[5] Though sequestrated from the small intestine, such segments are capable of sending off afferent pain stimuli when affected by such factors as ulceration.[6] There has been no evidence by history or repeated x-ray studies of any such difficulty in this group of patients.

One gratifying result of operation has been the postoperative weight gain in almost 70% of patients. However, this was not a matter of great concern, for the only possible detrimental metabolic effect of the operation is related to vagotomy and pyloroplasty. These effects have been well documented and, in the main, are not of great moment. The other aspect of the operation is the repositioning of a small segment of jejunum interposed between the esophagus and stomach. As the stomach is intact and the admixture of food, gastric juice, bile, and pancreatic juice occurs in normal sequence, any disturbance in metabolic processes would indeed have been surprising.

From the patient's viewpoint, the most important benefit of the operation is the ability to swallow without awareness of any abnormality. This was characteristic of the vast majority of patients. While it is true that some patients ate more slowly than normal, this was a minor annoyance in only three. This consequence of operation is not surprising, for the transit time of the passage of food through the normal esophagus aided by primary and secondary peristaltic waves is very rapid; when the food bolus reaches the jejunal segment, the latter is not neurogenically synchronized with the proximal esophagus. Consequently, food is carried from the esophagojejunal junction into the stomach by an intestinal segment with a slower peristaltic pattern. It is surprising that so few patients were aware of any abnormality of swallowing.

On the negative side, 14% of this group of patients exhibited a mild form of dumping syndrome which in no way affected their health. Probably, these symptoms are related to the pyloroplasty. Because the segment is short and the transit time rapid, the possibility of an osmotic effect seems remote.[7] In general, major surgical procedures alle-

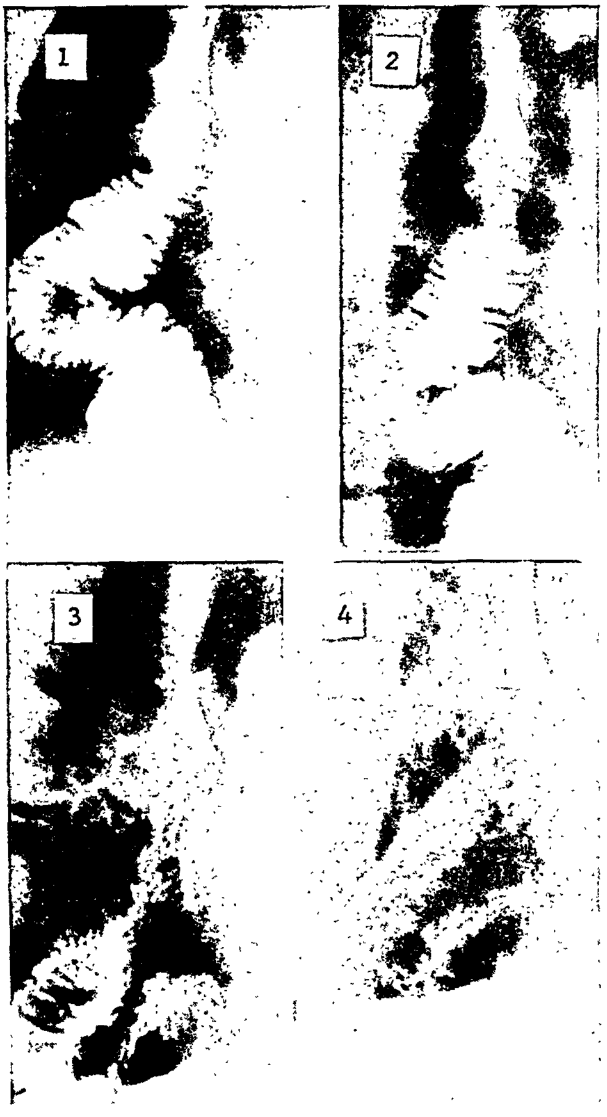

Fig. 4.—Views of swallowing sequence taken at two-second intervals, representing rapidity of action of jejunal segment interposed on June 3, 1952. Redundancy noted in chest has not increased over that existing in early x-rays and has been eliminated in majority of subsequent cases.

viate a major disorder and the patient endures some other minor symptoms. The advantages gained by the operative procedures seem to outweigh by far the minor complaints encountered thus far in this study.

As with many new operative procedures, one encounters a high mortality. Additional experience usually results in a betterment on this score, suggesting that certain deaths were preventable. The mortality of 12.1% in this series is high. However, no patient with the proper indications has been denied surgery in an attempt to define the proper place for this procedure. Errors in judgment, surgical technique, and postoperative care have been made. The clinical experience gained should be reflected in less risk to subsequent patients. Attention should be drawn, however, to the fact that one-third of the patients were in the sixth and seventh decades of life. Furthermore, these patients represent treatment failures on both medical and surgical grounds. In one-third of the patients, the interposition operation was the second, third, or fourth major operative attempt for alleviation of the patient's disease.

An additional factor worthy of comment in evaluating the risk of any operative procedure is related to the life history of the disease itself and the philosophy of the surgeon. The diseases for which this operation has been undertaken result in prolonged, severe disability and, frequently, death of the patient over a period of time if untreated. Our philosophy has been to accept a higher risk in this group of patients in order to obtain a cure of the disease.

Summary and Conclusions

Over a five and one-half year period, 33 patients with various "benign" lesions of the esophagus and cardioesophageal sphincter have been subjected to the jejunal interposition operation.

Certain features of the operative techniques have been emphasized to insure viability of the sequestrated and interposed segment, as well as preservation of diaphragmatic function. The operative mortality of this series was 12.1%.

The interposition of a physiological sphincter at the esophagogastric junction has prevented the occurrence of postoperative esophagitis after cardioesophageal removal in all of the patients followed up in this series. Ninety-six per cent of the patients were improved after the operation. Eighty-eight per cent were classified as showing an excellent result.

Normal swallowing was present in the majority of patients, with an incidence of 13.3% of late mild dumping syndrome and significant metabolic improvement reflected in an average weight increase of 14.1% in two-thirds of the patients.

The jejunal interposition operation, by its very design, is a sound physiological procedure which satisfies the need for a substitute esophagogastric sphincter. The resistance of the jejunal mucosa to peptic digestion, the prevention of esophagitis, and the excellence of the jejunum for transporting food support the findings of the same experimental preparation in the laboratory.

This study was supported, in part, by grants from the U. S. Public Health Service and Initiative 171 Funds from the State of Washington for Research in Biology and Medicine.

CLINICAL NOTES

DIRECT CORONARY ARTERY PERFUSION FOR AORTIC VALVE SURGERY

REPORT OF TECHNIQUE

Earle B. Kay, M.D., Louis R. Head, M.D.
and
Cid Nogueira, M.D., Cleveland

It has been apparent during the developmental phase of aortic valve surgery that further progress would come only when the aortic valve could be exposed for a sufficiently long period of time to allow for the proper evaluation of the pathological features and their definitive correction. In the past, partial correction with a high operative mortality has been obtained with the use of closed techniques or hurried procedures with the patient under hypothermia.

With the advent of extracorporeal circulation with the use of a mechanical pump oxygenator, 12 patients with aortic stenosis and regurgitation have been operated on during the past three years. If the patient was fortunate enough to have primarily fibrous aortic stenosis which could be corrected within a relatively short period of time, such operations could be successfully performed with use of elective cardiac arrest with potassium or acetylcholine and retrograde coronary sinus perfusion. However, if the valve was highly calcified or associated with regurgitation and the time required for the surgical correction of the stenosis and relief of the regurgitation by the addition of plastic cusps was greater than 20 minutes, then failure frequently ensued as a result of cardiac arrhythmias associated with the resulting myocardial anoxia.

There was no operative mortality in six patients in whom the cardiac arrest was 20 minutes or less, contrasted with an 80% mortality in those patients requiring more than 20 minutes. The greater myocardial anoxia associated with the longer period of aortic valve exposure undoubtedly was the factor largely responsible for the failure. However, the valves in such patients were also the most severely destroyed and the myocardial reserve probably the poorest. Unfortunately, one cannot foretell in advance the time that will be required for definitive surgery. Direct coronary artery perfusion, providing a well-oxygenated beating heart in the patient here reported on, allowed successful exposure and correction of the aortic valve throughout a 42-minute period.

Technique of Direct Coronary Artery Perfusion

In the laboratory it was found that aortic occlusion with and without cardioplegic drugs would allow successful exposure of the valve for a period of 20 to 30 minutes with a return of a normal beat in 75% of the dogs. In our experience, retrograde coronary sinus perfusion with arterialized blood did not increase either the safety or length of time over a 20-minute period that the aortic valve could be exposed. This technique also has the deleterious aspects of incomplete myocardial perfusion because of the anatomic arrangement of the coronary veins; in addition, it not infrequently causes considerable myocardial petechial hemorrhages.

It soon became apparent that to be successful in the majority of instances requiring longer periods of time for definitive correction of the lesion and to avoid the undesirable features of the other techniques, the hypertrophied myocardium in these damaged hearts must be kept well oxygenated and beating. Consequently, for the past two years we have been attempting to devise in the laboratory suitable cannulas for direct coronary artery cannulation and perfusion which does not interfere with the exposure of the aortic valve.

After many failures with various types of cannulas, a type was recently developed which appears to be suitable and which has been successfully used clinically. These cannulas, as demonstrated in the figure, consist of a set of two mounted on a flexible spring which gives rise to lateral pressure and which helps maintain the cannulas in place. This spring can also be adjusted to give maximum space between the cannulas to allow for aortic valve exposure. The main advantage of these cannulas consists in a movable flexible tip that adjusts itself to the coronary artery irrespective of the position of the remaining arm of the cannula. This tip joins the cannula by means of a ball valve which is the movable part and which fits snugly into the orifice of the artery and prevents the retrograde loss of blood. The cannulas are further maintained in position by a suture passed around the coronary artery, through the aortic wall, and around the cannula proximal to the ball valve. It is advisable to have at least two sizes of cannulas because of the variation in the size of the coronary arteries.

The pertinent aspects in the use of these cannulas for direct coronary artery perfusion during surgical correction in a patient with a combination of aortic stenosis and regurgitation are here described.

Report of a Case

A 30-year-old man, who weighed 180 lb. (81.6 kg.), had his first attack of rheumatic fever at the age of 15 years. He remained well until the age of 28, when he began noticing increasing dyspnea on exertion. He had both a systolic and a diastolic murmur over the aortic valve. The blood pressure ranged around 140/30 mm. Hg. The roentgenograms revealed an enlarged heart with severe left ventricular hypertrophy. The electrocardiogram revealed the presence of left ventricular overloading, a first degree atrioventricular block, and remote anteroseptal myocardial damage.

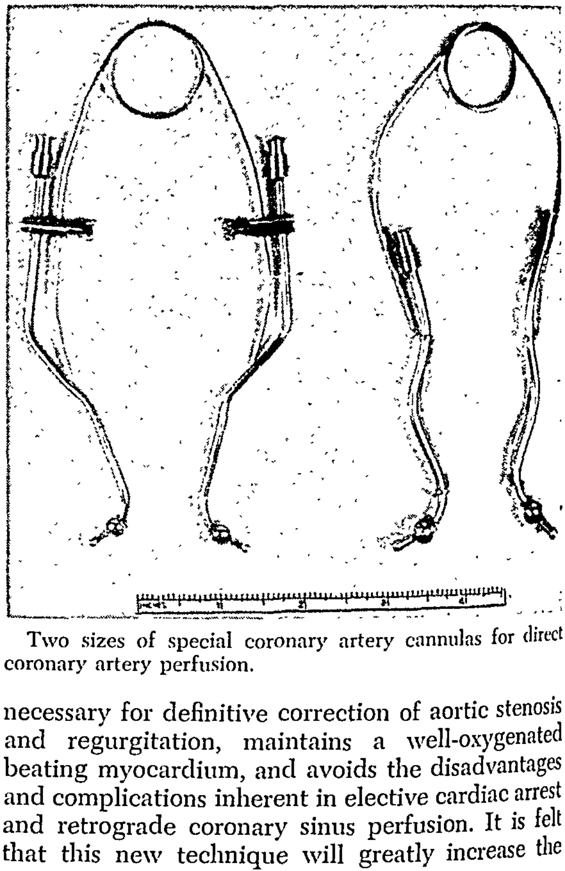
On April 24, 1958, the patient was operated on by means of extracorporeal circulation with the Kay-Cross rotating disk oxygenator. A harsh systolic thrill could be palpated in the base of the ascending aorta, which was markedly enlarged and measured 2 in. in diameter. Pressures in the aorta were 170/30 mm. Hg. The machine was then started with a perfusion rate of 3,500 cc. per minute. The ascending aorta was cross-clamped, 820 mg. of acetylcholine was injected, and the aortic valve was exposed through a Meyer's hockey stick incision. The coronary arteries were then cannulated and perfused with 150 cc. of arterialized blood per minute. This was gradually increased to 350 cc. per minute. After approximately one minute, normal cardiac rhythm was established and maintained throughout the procedure, which lasted for 42 minutes. The acetylcholine was used as a safeguard in the event that it might take unduly long to perform the coronary artery cannulations; its use probably is not necessary.

The aortic valve was highly calcified and showed evidence of both stenosis and regurgitation. Large chunks of calcium were removed from the left lateral and anterior cusps, which were also markedly shrunken and fibrotic. The other two commissures were widely opened. The posterior cusp was fairly pliable but tended to herniate toward the ventricular cavity. This cusp was supported in its anatomic position by sutures at the adjacent commissures, which also included the annulus. The regurgitation was then corrected by the addition of a cusp of compressed Ivalon (16 to 1 mm.) fixed by interrupted sutures to the aortic side of the left lateral and anterior cusps. This allowed for complete apposition of the cusps. The aortic incision was closed except for 1 cm. through which the cannulas were removed. The aortic suture was then finished, followed by removal of the aortic clamp and cessation of use of the machine. The mean arterial pressure as registered in the superficial femoral artery manometer continued to be 100 mm. Hg. Pressures again recorded in the ascending aorta were now 130/80 mm. Hg.

The patient's postoperative course was uneventful, and he has made an excellent recovery with relief of symptoms and a decrease in heart size. The blood pressure four months postoperatively was 140/100 mm. Hg.

Summary

Successful open aortic valve surgery has been limited in the past because of lack of a suitable technique for maintenance of an oxygenated myocardium and a beating heart which has necessitated hurried and partial valvular corrections. The technique of direct coronary artery perfusion through especially devised cannulas allows all the time necessary for definitive correction of aortic stenosis and regurgitation, maintains a well-oxygenated beating myocardium, and avoids the disadvantages and complications inherent in elective cardiac arrest and retrograde coronary sinus perfusion. It is felt that this new technique will greatly increase the success of aortic valve surgery.



Two sizes of special coronary artery cannulas for direct coronary artery perfusion.

10465 Carnegie Ave. (Dr. Kay).

THE CONSTIPATED COLON.—Most writers when writing about constipation begin their discourse by dividing the cases into two groups, one with a supposedly atonic colon and the other with a spastic colon. I am satisfied that this classification is without much basis in fact. For years I had roentgenologic friends watching for a case of what they could feel sure was atonic constipation, but they never found one for me. That is why, 40 years ago, I decided that the ancient division of constipated colons into the atonic and the spastic should be forgotten. As far as I can remember, it never helped anyone when treating constipation.— W. C. Alvarez, M.D., The Physiology of Constipation, *Diseases of the Colon & Rectum,* September-October, 1958.

INTOXICATION FROM PRIMIDONE DUE TO ITS BIOTRANSFORMATION TO PHENOBARBITAL

Gabriel L. Plaa, Ph.D., James M. Fujimoto, Ph.D.
and
Charles H. Hine, M.D., Ph.D., San Francisco

Primidone (Mysoline), 5-phenyl-5-ethylhexahydropyrimidine-4,6-dione, is an anticonvulsive agent which has been used successfully in the treatment of grand mal epilepsy and is reported to have controlled seizures in cases refractive to other anticonvulsant therapy. It is not an official drug, but was included in New and Nonofficial Remedies of 1957. It is marketed in oral tablets of 0.25 Gm.; the daily dose for adults is 0.5 to 1.5 Gm. It is a congener of phenobarbital, in that the oxygen on the second carbon has been reduced with hydrogen. In this respect it is similar to 2-dihydro 5,5-diphenylhydantoin, the congener of diphenylhydantoin, which was shown to be an effective anticonvulsant by Hine.[1]

Side-effects have been reported[2] to be more frequent than with phenobarbital and include the usual signs and symptoms of anticonvulsant drug toxicity, including dizziness, nausea, vomiting, ataxia, mood change, and pruritic rash. Toxic side-effects are stated to be controlled by reduction of dosage. However, its therapeutic status and toxic potentialities have not been entirely established. Its biotransformation in the body has not been completely elucidated, but a product identified as phenylethyl malonyl diamide has been identified in the urine of rodents receiving this compound, and recently Butler and Waddell[3] have published evidence that it is converted in part to phenobarbital in man and dog.

In the following report we are citing three cases of drug intoxication which have been observed in epileptics on a primidone regimen and suggest that the intoxication was principally due to the conversion of this compound in vivo to phenobarbital.

Case 1.—This 24-year-old housewife had had three previous admissions for diagnostic study, and had been followed in the outpatient clinic for a period of a year and a half. The symptoms 18 months previously were right-sided seizures with loss of consciousness. Electroencephalograms (EEG) repeated on several occasions were interpreted as being nonspecific; however, pneumoencephalograms suggested a space-consuming lesion in the left cerebrum. Her seizures had been partially controlled, being less frequent in number, with modification of the seizure pattern. Medication for the three months prior to the present admission included primidone, 250 mg. three times a day, and methoin (Mesantoin), 250 mg. in the morning.

On admission she was noted to be mentally confused, and she had a staggering gait, psychomotor retardation, and dysarthria. A bilateral horizontal nystagmus was noted, and anisocoria. Superficial reflexes were absent and knee and ankle jerks hypoactive. Other findings were not remarkable. EEG tracings appeared less stable than previously, and focal changes consisting of high-voltage irregularity and asynchronism appeared to center in the low frontal, procentral, and anterior temporal regions on the right. All medication was stopped on admission, and 24 hours later 5 ml. of blood was taken for drug analysis. The sample was analyzed by the method of Plaa and Hine.[4] The ultraviolet absorption curves after separation into the two fractions indicated the presence of a barbiturate and a hydantoin. Subsequent characterization of the barbiturate[5] indicated the presence of a compound with the ultraviolet characteristics of phenobarbital. The whole blood level of barbiturate was 4 mg. %. The hydantoin level was below that capable of quantitation by this method (0.2 mg. %). Four days later, the patient had become asymptomatic and free of her presenting signs and symptoms. The medication was readjusted to include diphenylhydantoin and mephobarbital (Mebaral).

Case 2.—This 8-year-old child was admitted to the pediatric service of the University of California Hospital in December with the chief complaint of seizures. These had first commenced at the age of 4 and had gradually increased in frequency until they were described as occurring "every few minutes" during waking hours, especially when the patient was inactive. Physical examination on admittance indicated a well-developed, thin, mildly retarded boy in no distress. The skin revealed a small abrasion of the left forehead and lower lip; enlarged cervical and inguinal lymph nodes were present; the skull revealed no deformity; the pupils were round, regular, equal, and reacted to light; extraocular movements were normal; fundi revealed no pathology. Neurological examination was physiological. Hemogram indicated hemoglobin level of 14 Gm. per 100 cc. and white blood cell count, 10,000 per cubic millimeter, the differential showing 25% eosinophils. Routine tuberculin and Schick tests were negative; repeated urine analysis was not remarkable, nor was lumbar puncture. Stools contained Endolimax nanacysts. Psychometric examination indicated a full-scale IQ of 65, according to the Wechsler intelligence scale for children.

During the first 45 days of the 65-day hospital course, seizures were frequent and difficult to control. Medication was repeatedly readjusted in an effort to arrive at an adequate combination. On the 46th hospital day, he was placed on therapy with primidone, 250 mg. twice a day, which was subsequently increased to three times a day; diphenylhydantoin was added to the regimen. On Feb. 7 an additional 125 mg. of primidone was given at bedtime; on Feb. 8 phensuximide (Milontin) was also given, 500 mg. three times a day. On Feb. 9 all therapy was discontinued, since ataxia and generalized incoordination indicated possible drug intoxication. The barbiturate level in the blood was 5.8 mg. % at this time, and the ultraviolet absorption characteristics again indicated phenobarbital.

Case 3.—This 4½-year-old boy was first admitted to the University of California Hospital in February. His chief complaint was convulsions. The history furnished by his mother indicated that there had been no neonatal complications and that he had been born after uncomplicated labor and delivery, weighing 7 lb. 12 oz. (3,515 Gm.). He had done well until six months previously, when he suddenly developed seizures characterized at first by foaming at the mouth and

---

loss of consciousness for 15 to 30 seconds. The seizures occurred approximately 20 to 30 times a day. He was started on therapy with phenobarbital, which was replaced in a month's time by diphenylhydantoin, 50 mg. three times a day; trimethadione (Tridione), 50 mg. four times a day; and phenobarbital, 30 mg. four times a day. Convulsions increased in frequency, however, and he started having focal seizures involving the right side of his mouth and the right arm and leg. He had been hospitalized four months earlier in another hospital, where a pneumoencephalogram and skull x-ray did not clarify the clinical picture. He was maintained on therapy with the above drugs and did fairly poorly, having 10 to 12 seizures a day. A number of medicaments were tried with varying degrees of success. He had been on therapy with primidone, 750 mg. daily, phensuximide, 500 mg. daily, and phenobarbital 45 mg. daily, with restriction of salts and fluids, for two months prior to admission. During the past six weeks his speech had been slurred and he had been ataxic. He was referred for regulation of his medication and treatment of possible drug intoxication. He improved rapidly in the ward, and in one week's time his ataxia and slurred speech disappeared and he had no seizures. Blood analysis for therapeutic agents 24 hours after admission indicated the presence of a barbiturate. Ultraviolet absorption characteristics were similar to those of phenobarbital and the whole blood level was 4.0 mg. %.

Experimental Work

Since these findings indicated a possible biotransformation of primidone to a barbiturate resembling phenobarbital, limited experimental work was initiated to gather further evidence of this biotransformation. The ultraviolet characteristics of primidone excluded the possibility of interference by this compound with the absorption spectra of phenobarbital.

A group of rats was injected daily with 100 to 150 mg. of primidone and the urine was collected for five days. A portion of the urine was acidified and extracted several times with chloroform. The chloroform extracts were then combined and washed with phosphate buffer, pH 7.5. The chloroform was extracted with dilute sodium hydroxide; the alkaline extracts were acidified and further extracted with chloroform. The final chloroform extracts were evaporated to dryness. Paper chromatograms of the residue were prepared, according to the procedure of Algeri and Walker.[6] Subsequent contact ultraviolet photography of the dried chromatograms resulted in development of a spot in that position normally occupied by phenobarbital. Alkaline elution of this zone with subsequent determination of the ultraviolet spectra and absorbence ratios indicated that this zone contained a barbiturate with the ultraviolet characteristics of phenobarbital.[7]

Comment

Our data give good presumptive evidence that primidone is metabolized, in man and rats, to a barbiturate and that this barbiturate is, or closely resembles, phenobarbital. Our findings coupled with Butler's observation in man and dog[3] leave little doubt that the metabolite is phenobarbital.

Whenever a patient is treated on an ambulatory basis, there is a possibility that the patient had access to other drugs and is reluctant to admit their use. This possibility was present in cases 1 and 3. In case 2, however, the possibility that phenobarbital was ingested is absent, since the patient was hospitalized during the entire course of therapy with primidone.

From our own studies[8] on blood levels of phenobarbital in epileptics, we have found that the level determined in each of these cases is compatible with the signs of barbiturate intoxication. In case 3, the patient was taking 45 mg. of phenobarbital daily in addition to the primidone. However, by our methods of analysis this amount would be barely detectable normally (about 0.2 mg. %), consequently the 4.0 mg. % measured must be a reflection of the phenobarbital contribution from the biotransformation of the primidone (250 mg. three times a day).

In our opinion, the biotransformation of primidone to phenobarbital was the cause of the observed drug intoxication in these three cases. It was noted that the signs of toxicity did not occur on commencement of the regimen, but took a matter of weeks to develop. Whether this time lag reflects an accumulation of phenobarbital or an increased percentage transformation of primidone to phenobarbital remains to be elucidated. Whether the anticonvulsant properties of primidone are due to this biotransformation also remains to be determined.

Finally, we recommend that anticonvulsant regimens of primidone be evaluated by the physician in terms of the potential drug intoxication through its biotransformation to phenobarbital.

COUNCIL ON DRUGS

NEW AND NONOFFICIAL DRUGS

Monographs and supplemental statements on drugs described here and in subsequent editions of New and Nonofficial Drugs are based on the evaluation of available scientific data and reports of investigations.

H. D. Kautz, M.D., *Secretary*.

Rabies Vaccine (Duck Embryo).—A sterile, freeze-dried suspension of killed rabies virus prepared from whole duck embryo infected with this virus, chemically inactivated, and preserved with 1:10,000 thimerosal. Rabies vaccine (duck embryo) is standardized for potency by active immunization of mice according to specifications of the National Institutes of Health.

Actions and Uses.—Rabies vaccine (duck embryo) is used prophylactically for active immunization against rabies, usually during the incubation period after exposure. Its immunizing capacity compares favorably with that of older vaccines prepared from animal nervous tissue; prompt antibody responses are produced after subcutaneous injection of the duck embryo preparation. The indications for or against giving rabies vaccine frequently are difficult to define because of the impossibility of determining what exposure has actually occurred. In determining whether to institute vaccine therapy, the following factors should be taken into consideration, as opposed to the risk of paralytic or other complications from the vaccine itself: 1. Approximately 20% of persons bitten by animals known to be rabid have developed rabies if not treated with rabies vaccine. 2. If clinical symptoms of rabies develop, the disease is 100% fatal; there is no specific therapy. 3. Rabies rarely occurs unless the person actually has been bitten by the animal. The need for treatment must be weighed against the risk of the treatment itself. In general, the management of patients exposed to supposedly rabid animals should follow the recommendations set forth by the Expert Committee on Rabies of the World Health Organization (WHO Technical Report Series, No. 121, 1957).

Aside from the inconvenience of daily injections and the occurrence of local reactions, the principal deterrent to the use of the older nervous tissue vaccines has been the danger of severe neurological or paralytic phenomena. These have included peripheral neuritis, dorsolumbar myelitis, and acute ascending spinal paralysis. Such reactions result from sensitization to foreign brain tissue rather than from sensitization to the fixed virus antigen. Since experiments have shown that duck embryo tissue contains little, if any, of the "paralytic factor," it is believed that the danger of neurological side-effects is materially reduced by the use of the duck embryo vaccine.

Mild to severe local erythematous reactions have been observed in about one-third of the patients to whom rabies vaccine (duck embryo) has been administered. In addition to the local erythema, patients may exhibit inflammation and induration at the site of injection, regional lymphadenopathy, and, occasionally, giant urticaria. Much more rarely, a systemic type of reaction characterized by malaise, febrile episodes, and chills may be observed. Although cross sensitization between duck protein and chicken protein is rare, caution should be observed in administering the duck embryo vaccine to persons known to be sensitive to egg, chicken, or chicken feathers. From the standpoint of overall clinical safety, the duck embryo vaccine is considered to be a decided improvement over the older rabies vaccines prepared from the nervous tissue of animals.

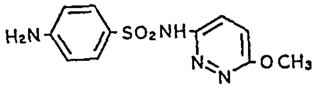
Dosage.—Rabies vaccine (duck embryo) is administered subcutaneously. The freeze-dried powder is mixed with sterile water for injection; 1 cc. of the resulting suspension is injected beneath the skin of the abdomen each day for 14 days. A 23-gauge or 24-gauge needle, approximately one-half to three-fourths inches long, should be used and the site of injection varied for each dose.

Preparations: powder (injection) yielding one dose with 1 cc. of sterile diluent.

Applicable commercial name: Rabies Vaccine (Duck Embryo).

Eli Lilly & Company cooperated by furnishing scientific data to aid in the evaluation of rabies vaccine (duck embryo).

Sulfamethoxypyridazine.—N ^{1}-(6-Methoxy-3-pyridazinyl)sulfanilamide.—3-Sulfanilamido-6-methoxypyridazine.—The structural formula of sulfamethoxypyridazine may be represented as follows:



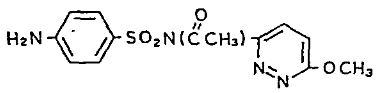
Actions and Uses.—Sulfamethoxypyridazine is of value for the chemotherapy of urinary tract infections and systemic infections due to micro-organisms susceptible to the bacteriostatic action of sulfonamides. The drug is rapidly absorbed from the gastrointestinal tract and is conjugated to a minimal degree in the body; 40 to 70% of the total blood sulfonamide is present in the acetylated form; 30 to 60% of the administered dose is excreted in the urine in the free form. Sulfamethoxypyridazine is distinguished from other sulfonamides by its exceptionally slow rate of excretion. Maximum blood levels are reached within a few hours after the oral administration of 1 Gm., and this high level is maintained for about 10 hours. Thereafter, blood levels fall slowly; at the end of 24 to 48 hours, blood levels are about half of the maximum. After 96 hours they reach one-eighth to one-fourth the maximum levels. Because of this long duration of action, lower dosage and less frequent administration are required than with other sulfonamides.

Except for a diminished incidence of renal toxicity, the same general type of side-effects and untoward reactions may be expected with sulfamethoxypyridazine as with other sulfonamides. Hence, the drug should be used with the same precautions and is subject to the same contraindications as other agents of this class. (See the general statement on sulfonamides in New and Nonofficial Drugs.)

Dosage.—Sulfamethoxypyridazine is administered orally. Since it produces high, prolonged blood levels, it is imperative that the recommended doses, which are much lower than with other sulfonamides, are not exceeded. For mild to moderate infections, the initial dose for adults is 1 Gm. the first day, followed by 500 mg. every day thereafter or 1 Gm. every other day. In severe infections, as much as 2 Gm. may be given to adults on the first day, followed by 500 mg. every 24 hours. Dosage for children is reduced in proportion to body weight. Therapy should be continued for five to seven days or until the patient is asymptomatic for 48 to 72 hours.

Preparations: tablets 500 mg.
Applicable commercial names: Kynex, Midicel.
Lederle Laboratories Division, American Cyanamid Company, cooperated by furnishing scientific data to aid in the evaluation of sulfamethoxypyridazine.

Acetyl Sulfamethoxypyridazine. — N^1-Acetyl-N^1-(6-methoxy-3-pyridazinyl)sulfanilamide. — 3-(N^1-Acetylsulfanilamido)-6-methoxypyridazine. — The structural formula of acetyl sulfamethoxypyridazine may be represented as follows:

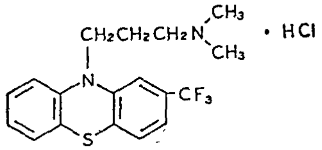


Actions and Uses.—Acetyl sulfamethoxypyridazine has the same actions and uses as the parent sulfonamide, sulfamethoxypyridazine, except that it is tasteless and is therefore better suited to pediatric use as a liquid medication. (See the monograph on sulfamethoxypyridazine.)

Dosage.—Acetyl sulfamethoxypyridazine is administered orally. The dose for children is 250 mg. for each 20 lb. (9 kg.) of body weight and is given immediately after a meal on the first day. Thereafter, the dose is 125 mg. per 20 lb. of body weight, given immediately after a meal once daily or, alternatively, 250 mg. per 20 lb. of body weight every other day. For children weighing 80 lb. (36.3 kg.) or more and for adults, the dose of acetyl sulfamethoxypyridazine is the same as for the unacetylated drug, sulfamethoxypyridazine.

Preparations: suspension (oral) 25 mg. per cc.
Applicable commercial name: Kynex Acetyl.
Lederle Laboratories Division, American Cyanamid Company, cooperated by furnishing scientific data to aid in the evaluation of acetyl sulfamethoxypyridazine.

Triflupromazine Hydrochloride. — 10-(3-Dimethylaminopropyl)-2-(trifluoromethyl)phenothiazine hydrochloride.—The structural formula of triflupromazine hydrochloride may be represented as follows:



Actions and Uses.—Triflupromazine hydrochloride is identical in chemical structure to chlorpromazine hydrochloride except that it contains a trifluoromethyl group rather than a chlorine atom at the 2 position of the phenothiazine ring. It is perhaps more closely allied in actions and uses to chlorpromazine than any of the other phenothiazine derivatives currently in use. Equivalent pharmacological and clinical responses can be elicited with doses of triflupromazine that are less than those of chlorpromazine, thus indicating a greater potency for the former compound.

Triflupromazine is useful as an adjunct to the management of various acute and chronic psychoses, particularly those associated with excessive psychomotor activity and overt hostility as in schizophrenia, mania, senile and toxic psychoses, and in alcoholism. The drug is reported to ameliorate such psychic symptoms as hallucinations and delusions and to control agitation, anxiety, tension, panic, hostility, and aggressiveness in appropriate cases. It is also of value in facilitating rapport with the psychiatrist and making the patient more amenable to psychotherapy. The drug should not be given to patients with depressive-obsessive states, nor is it intended for use in simple neuroses or relatively minor emotional disorders. In common with other phenothiazine compounds, triflupromazine exerts a significant antiemetic effect and is effective for the control of nausea and vomiting of varied etiologies.

In general, triflupromazine seems to compare well with chlorpromazine, with respect to the overall incidence of side-effects and untoward reactions. Phenothiazine-induced jaundice associated with triflupromazine has been exceptionally rare. Only one reported instance of granulocytopenia associated with the administration of triflupromazine has been reported. In view of the phenothiazine structure of triflupromazine, physicians using this drug should be alert to signs of hematopoietic depression; routine blood cell counts are advisable during therapy. Excessive sedation and drowsiness are apparently less with triflupromazine than with chlorpromazine; hypotension and tachycardia may also occur somewhat less frequently. The most common side-effect to the drug is a parkinsonian syndrome, with motor disturbances and extrapyramidal symptoms. This reaction generally subsides upon reduction in dosage and/or administration of an antiparkinsonian drug. Other reported side-effects include blurring of vision, dizziness, nausea, epigastric distress, weakness, weight gain, insomnia, allergic reactions, and photosensitivity. Triflupromazine is contraindicated in patients under the influence of large amounts of alcohol, barbiturates, or opiates.

Dosage.—Triflupromazine hydrochloride is administered orally and, occasionally, intramuscularly or intravenously. Optimal dosage varies from patient to patient and should be determined on an individual basis. For adults, the usual initial oral dose is 25 mg. three times daily. This dose may then be increased gradually until a satisfactory clinical response has been obtained or until side-effects become a problem. For children and geriatric patients, the usual oral dose is 10 mg. three times a day.

For rapid effect in severely agitated patients or in severe nausea and vomiting, triflupromazine hydrochloride may be given parenterally. Dosage by the intramuscular route ranges from 20 to 50 mg. three times a day; single intravenous doses range from 2 to 10 mg. Oral therapy should be substituted for parenteral injection as soon as feasible.

Preparations: emulsion (oral) 10 mg. per cc.; solution (injection) 20 mg. in 1 cc.; tablets 10, 25, and 50 mg.

Applicable commercial name: Vesprin.

E. R. Squibb & Sons, Division of Olin Mathieson Chemical Corporation, cooperated by furnishing scientific data to aid in the evaluation of triflupromazine hydrochloride.

Use of Nicotinic Acid in Hypercholesteremia

The Council was requested to evaluate the usefulness and safety of large oral doses of the vitamin, nicotinic acid (Niacin), for the treatment of hypercholesteremia. The rationale for such use of the drug stems from the statistical relationship which is commonly accepted to exist between elevated serum cholesterol levels and the clinical manifestations of atherosclerosis. There seems to be little doubt that nicotinic acid, when given in large doses to hypercholesteremic subjects, will frequently bring about a marked reduction in cholesterol levels; the lowering of cholesterol is less impressive in subjects with normal or near normal levels. Theoretically, sustained reduction of circulating cholesterol levels appears to be desirable. However, to date, there is no valid evidence that lowered blood cholesterol levels cause clinical improvement of the patient. Although the large doses of nicotinic acid (3 to 6 Gm. per day) employed for the treatment of hypercholesteremia have not been associated with serious toxic effects, the possibility of adverse reactions should be kept in mind. Pending the accumulation of evidence to show a bona fide beneficial effect in patients, either from the viewpoint of prophylaxis or therapy of atherosclerotic cardiovascular disease, the use of nicotinic acid for purposes other than the prevention or treatment of pellagra must be considered experimental.

The Council voted to expand New and Nonofficial Drugs to describe the use of nicotinic acid in hypercholesteremia.

Eli Lilly & Company cooperated by furnishing scientific data to aid in the evaluation of this additional use of nicotinic acid.

INCREASING IMPORTANCE OF INFECTION AFTER BURNS.—A review was made of the cases of 93 patients with burns covering more than 20 per cent of the body surface who were treated at the San Francisco City and County Hospital, University of California Service, between 1943 and 1956. The mortality rate increased from 40 per cent during 1943-1947 to 69 per cent during 1952-1956. A significant change in survival time was noted: During 1943-1947, 69 per cent of the deaths occurred within 48 hours of admission; during 1952-1956, only 19 per cent of the deaths occurred within the first 48 hours. In the period 1943-1947 the majority of deaths resulted from shock in the immediate post-burn period; in the later years of the study the major cause of death was infection. . . . No patient who had a blood culture positive for bacteria survived. The use of antibiotics had no effect on the incidence of infection. Elderly patients, children and alcoholics were less able to resist the effects of infection.—A. G. Clark, M.D., and J. H. Hanson, M.D., Mortality Rates in Patients with Burns: A Report of Experience at San Francisco City and County Hospital, 1943-1956, *California Medicine*, September, 1958.

isms susceptible to the bacteriostatic action of sulfonamides. The drug is rapidly absorbed from the gastrointestinal tract and is conjugated to a minimal degree in the body; 40 to 70% of the total blood sulfonamide is present in the acetylated form; 30 to 60% of the administered dose is excreted in the urine in the free form. Sulfamethoxypyridazine is distinguished from other sulfonamides by its exceptionally slow rate of excretion. No patient who had a blood culture positive for bacteria survived. The use of antibiotics had no effect on the incidence of infection. Elderly patients, children and alcoholics were less able to resist the effects of infection.—A. G. Clark, M.D., and J. H. Hanson, M.D., Mortality Rates in Patients with Burns: A Report of Experience at San Francisco City and County Hospital, 1943-1956, *California Medicine*, September, 1958.

COUNCIL ON FOODS AND NUTRITION

The following is one of the six papers presented at the symposium on "Nutrition in Pregnancy" in Columbia, Mo., Oct. 11, 1957. This symposium was sponsored by the Council on Foods and Nutrition, with the cooperation of the Boone County Medical Society, the University of Missouri School of Medicine, and the Adult Education and Extension Service of the University of Missouri.

PHILIP L. WHITE, SC.D., *Secretary,*

MATERNAL NUTRITION AND THE FETUS

Ray Hepner, M.D., Columbia, Mo.

Each generation has a genetic and environmental background of experience, even at birth. The constant improvement in livestock production has proved the practicality of research applied to reproductive problems in mammals. Human losses in the newborn period are now the third leading medical cause of death in the United States, and these statistics exclude stillbirth, miscarriage, and surviving damaged children. When prematurity, stillbirth, and the great tragedy, the surviving damaged child, are considered, together with unnecessary maternal illness and morbidity or death of liveborn children, we find ourselves faced with an immensely complex, yet perfectly interrelated, problem. No doubt exists about the role of nutrition in the problem, but solid evidence to support this belief has been singularly difficult to marshal. This presentation offers, first, some of the difficulties in studying the problem; second, the results of some studies of the past; and, third, some incompletely developed, yet fundamental concepts.

It is axiomatic that fetal problems are the best index to obstetric practice. This index may be as confined as the neonatal death rate alone, or, and perhaps more properly, it may be as broad as the entire gamut of reproductive problems. This gamut ranges from sterility, pregnancy and labor complications, miscarriage, premature and immature birth, stillbirth, and malformation to a functional abnormality that may become manifest well beyond the newborn period in the form of convulsions, defects of intellect, and neuromuscular disturbances.[1] These latter defects are known to the laity as epilepsy, feeblemindedness, and cerebral palsy, and, by the most conservative estimates, persons so affected make up at least 1% of our population today. Every indication is that this proportion will increase if the present production and survival rates of these children prevail.

Many studies have shown that nutrition plays a part in reproductive problems. Observations of war starvation in pregnancy,[2] of nutrition surveys in pregnancy,[3] of patients admitted to sterility and other special clinics, and of controlled animal investigations affirm this part.[4] A sufficient degree of starvation will cause sterility and amenorrhea that will not respond to adequate caloric intake until sufficient protein is provided. Attempts to reduce stillbirth, premature birth, malformations, and neonatal death in special prenatal clinics are impressive when one sees how much can be done to help the individual mothers of each group in which a nutritional deficit is demonstrated. For instance, the sterile mother can be helped to conceive; the habitual aborter can be helped to carry a child to viability; the repeated bearer of stillborn infants can be helped to have a living child.

Even with these known and measurable accomplishments, there is little change in the total statistical results in each hospital. The failure of statistics to improve may well be due to the use of an improper base line, one that is chased from one category to the next. To compare the incidence of premature birth with total viable births fails entirely to recognize those women who have conceived who did not conceive before, those who have carried a fetus to viability who could not before, and those who carried their fetuses to term who never did before. Our statistical base line might better be placed on a level with the reproductive group as a whole than compared with the final result, which, after all, is a goal to be achieved and not the point at which to begin. For a baby to be born alive at term and go home with its mother is not enough. Real success must be measured by achievement of the potential to become a contributing member of society.

Children handicapped by convulsions, neuromuscular problems, or a mental deficiency are born commonly to mothers with reproductive histories of sterility, miscarriage, stillbirth, pregnancy complications, premature or immature birth, and malformation. The prevailing view has been that this relationship is based on genetic fault.[5] Good evidence is available now which shows that inadequate nutrition can produce defects of function as

well as of structure.[6] Nutritional deficiencies may be related to any of the entire gamut of reproductive problems.

General Factors Influencing Reproduction

Apparently unrelated agents may produce injuries similar to those produced by a nutritional deficit. Trace elements, as well as major minerals, insulin, some infectious diseases, various corticoids, hypoxia, hyperoxia, vitamin excesses and deficiencies, and genetic faults can influence the reproductive spectrum. Repeated demonstrations both in man and in controlled animal experiments have shown that identical, or nearly identical, abnormalities may result from entirely different agents. A classic example in humans is found in the microcephalia of genetic fault and pelvic x-irradiation. In animals, the demonstration of identical bony defects in rats injured by riboflavin deficiency, x-irradiation, or inbreeding serves admirably for illustration.[7] Although different injurious agents may operate finally through similar pathways, the initiating agent remains different. Even so, the contributions of adequate nutritive stores may protect the organism against a considerable onslaught.

Nutritional Factors Influencing Reproduction

The concepts of timing, severity, type, and duration of nutritional deficit are of major import, since these factors often determine what part of the reproductive gamut is to be affected. In humans, acute starvation with protein depletion over a short period has been proved to be associated with a decrease in conception rate, and sterility with amenorrhea is produced over a longer starvation period. If acute depletion begins after conception, the babies are small. However, only inconclusive evidence of an increased incidence of malformation could be found in a previously well-nourished population.[2a] Some evidence of increased reproductive problems can be found in several studies of humans living on chronically poor diets, particularly when the stress of continued growth and the depletion of repeated pregnancy are added burdens.[3] These patients run the gamut of reproductive problems. On the basis of insufficient amounts and variety of good quality foods, these diets were assessed as poor, even though sufficient (and often more than sufficient) calories were provided. The frequency of obesity in the patients of these studies suggested the aphorism "overfed and undernourished," and the offspring of these women, when compared with controls, suffered as well.

In several animals, vitamin A deficiency is associated with sterility, abortion, malformation, stillbirth, or small young, depending on the duration, severity, and timing of the deficiency.[8] In rats, similar effects have been produced by deficiencies of pure thiamine, riboflavin, pyridoxine, or pantothenic acid without protein deficiency.[9]

Results of Past Studies

More than one-third of lethal human malformations involve the nervous system. However, many anomalies of the nervous system are compatible with life. Brain function is often seriously disturbed, with little or no demonstrable structural abnormality. For many years speculation has been forwarded that agents known to produce structural alteration with related defects of function might, in smaller doses, produce defects of function without histological abnormality.

In 1951 Whitely, O'Dell, and Hogan[6a] demonstrated that folic acid deficiency in pregnant rats could disturb the ability of the offspring to learn a standard maze, even though brain structure was apparently normal. More recently, doses of x-irradiation, smaller than necessary to produce anomalies of the nervous system of fetal rats, have produced similar results. Again, different agents have been proved able to produce a similar defect, but this defect is one of function rather than of structure.

The recent study of Harrell, Woodyard, and Gates[6b] is of special interest for two reasons. The first is that their assay of results was based on significant differences in intellectual performance of human offspring, a function that might be damaged even in the absence of a gross anatomic abnormality. Second, the dietary supplements used were thiamine, riboflavin, niacinamide, and iron—factors almost invariably missing from poor diets, particularly those poor in protein. This experiment, then, might tend to separate the effects of poor diet from the effects of the trace materials found in good foods. Unfortunately, no data are available about other differences in results in the two groups. Furthermore, supplementation was offered late in pregnancy, and only the latter parts of gestation could be affected. Even so, this approach, if verified, may have some practicality, in that food fortification is easier than changing the dietary habits of an entire population, although the latter method is unquestionably superior.

Interrelationship of Factors Affecting the Fetus

The interdependence of the many agents known to affect the embryo and fetus is more apparent as investigation continues. Our knowledge of antagonism, competition, and interrelationships of drugs, hormones, chromosomal determinants, enzymes, trace elements, amino acids, and vitamins is broadening rapidly. The assurance of balance in dietary supplementation by high quality foods is great, whereas the principal assurance of supplementation by single factors is that imbalance is to be expected.

Interrelationship of Nutritive Factors

Long ago it was said that no professor's hemispheres could supply adequate nutrition to the infant as well as the mother's own mammary hemispheres. Perhaps this remark is the clinician's way of saying that the demands of growth reveal rapidly almost any defect of nutrition. Although the pregnant woman ingests foods not only to maintain herself but to store some elements and support the growth of her uterus, placenta, membranes, and baby, it is the baby who, once out of the uterus, has the greatest demands and serves as the best example. Although artificial feeding of human infants is safe today, and the results are comparable with natural feeding, the history of difficulties in preparation of safe, adequate substitutes for natural feeding is punctuated by difficulties with anemia, digestibility, increased susceptibility to rickets and to infections, chloride acidosis, hyperphosphatemia, tetany, and pyridoxine deficiency. Debate on the various constituents of artificial feedings continues. No doubt exists about the value of controversy backed by careful observation of controlled studies. Our need is for properly developed and properly challenged evidence. In the entire field of nutrition, good evidence, at least so far, is slow to unfold and not easy to interpret. The principal lessons to be learned by surveying the mass of new information on interrelationships of nutritive factors are a humble respect for nutritive balance in foods and a healthy skepticism of indiscriminate administration of single supplements.

Dietary Problems in the United States

Although our food consumption as a nation statistically proves us to have the best fed population on earth, and although surveys of nutrition in pregnancy in the United States are commonly negative because of an insufficient number of ill-nourished mothers, some segments of our childbearing population take borderline or lesser amounts of high quality foods. The incidence of abnormalities in the reproductive gamut of these people has been increased; however, some studies [10] indicate that it may be reducible by dietary supplementation. At least four barriers to easing the problem exist: eating habits passed from generation to generation; high cost of some commonly recommended, good quality foods; social pressures from companions; and ineffective lay education. Several studies have shown that, even with marked improvement of economic status, poor dietary habits tend to persist.[11] It is true that some commonly recommended, high quality foods, particularly animal protein, are more expensive; however, a casual stroll through a grocery store can be reassuring. A quart of whole milk costs about the same as a carton of six small bottles of carbonated beverage, and dry skim milk is still less expensive. The same weight of standard brands of peanut butter versus jelly or jam sells for the same price. Perhaps some of the social pressures on the prematernal group compound the problem. The popularity of the soft drink–chips–candy bar luncheon and snack and the current demands of clothing styles for extreme slenderness can wreak nutritional havoc on the prematernal teen-ager, who is pressed on the one hand by growth needs and on the other by the demands of pregnancy. Some realistic competition could be given the pop-and-chips regimen by milk dispensers; fruit, sandwich, and low-priced nut dispensers could compete with candy bar, chewing gum, and chips machines. These competitive devices exist and are occasionally observed in commercial use on the American scene. An effective program of lay education could make the battle of the commercial machines at least self-supporting and, even better, begin to break some poor patterns of eating at home. A more effective program of lay education is needed. Skilled personnel trained to break the inertia of the problem need to be found, and medical school programs must, because of the place of the physician in society, lead this nurture of the prophylactic concepts of reproduction, growth and development, and health and environment.

Role of Placenta in Fetal Problems

Evidence of the effect of maternal nutrition on the fetus is often studied, but the connecting link between mother and fetus, the placenta, has had little attention. We examine the mother by indirection, the fetus as allowed, and leave the all-important conveyor in dim light. The placentas of women with renal disease, hypertension, diabetes, and true toxemia are often abnormal, and the fetuses of these pregnancies are known, by any criterion, to have problems. The role of the placenta in true toxemia of pregnancy still is debated, even as a possible cause, and the role of the placenta in the fetal problems of abnormal pregnancy has received little consideration. Therefore, it is not unexpected that scanty mention has been made of placenta abnormalities in otherwise normal pregnancies producing abnormal fetuses. The concept that placental insufficiency is responsible for the syndrome o postmaturity has aroused interest.[12] Flexner and co-workers [13] reported marked differences in placental blood flow in various abnormal pregnancy states. Recent observations suggest that, because o intrauterine malnutrition, placental abnormalitie per se may play a role in some instances of pre maturity and immaturity.[14] It might seem justified to speculate that abnormalities of placental func tion may be of far greater significance than so fa supposed.

Problems in Classifying Neonates

The newborn infant is judged by the crudes methods. Marked individual differences in so-called normal infants are found, and none but the grosse structural abnormalities, particularly the important ones of the cardiac, renal, and nervous systems, are identifiable during the neonatal period. Although weight is used as a standard reference point, it is a poor index whether used for maturity, growth, or body composition. The wide variability of total body water in the newborn infant has been demonstrated by Friis-Hansen,[15] but no general agreement about the significance of this variability has been reached by clinicians. Little use has been made of normal growth curves for length in early life, even though serial measurement of length is a better index of true growth. In addition, the pitfalls of differing body composition are excluded. Good methods for estimating iron stores of the individual infant are lacking, and no safe, practical, and generally accepted means of estimating calcium stores or body protein mass in the newborn infant are available. Tedious individual studies of small numbers of infants have recorded large individual differences in retentions of these basic substances. These various differences serve to underline some of our inadequacies to judge the newborn infant, even under the best of circumstances. Pregnancy histories including incidence of anemia, toxemia, and premature births, age of mother, number of pregnancies, and defective dietary habits are useful for planning each infant's nutritional management, but they can only be used circuitously to judge the adequacy of the gestation by its product. Repeated examinations through the first years of life, with special attention to linear growth and the rapid development of the nervous system in all its functions, are needed before an accurate opinion of an infant can be made. However, this opinion fails to separate the intrauterine from the extrauterine factors. Practical methods and normal standards must be established to provide a meaningful classification of infants in the newborn period.

Summary

Loss of human life in the newborn period is the third leading medical cause of death in the United States. The problems of reproduction—sterility and abortion, premature or immature birth and stillbirth, toxemia, labor problems, anemia in the mother during pregnancy and, in the first year, in the offspring, as well as malformations and neurological disorders of function—can be related and considered together.

Prematurity, immaturity, surviving malformed children, unnecessary maternal illness during pregnancy and puerperium (including failure of natural feeding) make a tremendous and, in large part, needless burden. Some neurological defects in children, the convulsive, mentally deficient, and so-called cerebral palsied, may be related to nutritional factors, and human and animal studies suggest that all defects enumerated here can arise from nutritional deficiencies. However, injurious agents other than nutritional deficiencies can produce reproductive problems indistinguishable from those of nutritional origin. The same deficit of nutrition may produce many different effects on the reproductive gamut, depending on timing, severity, and duration of the deficit.

No single element of nutrition holds the key. Balance of foodstuffs, with emphasis on high quality foods, would seem to be the preferred approach. Effective nutritional protection of the fetus begins long before conception and must continue throughout the childbearing period. Further investigation of the role of the placenta in the reproductive process seems in order, and better methods and normal standards for the evaluation of newborn infants are needed. A long-range educational program about the value of nutritional protection is needed for the coming generation, in medical schools, and for the public at large. The nutritional approach to the problems of reproduction can be more effectively used, both in practice and in investigation.

DIAGNOSTIC PROBLEMS

GENERALIZED ABDOMINAL PAIN AND ACUTE RENAL FAILURE

Clinical Pathological Conference (PM 1228-56), Feb. 7, 1957, from the Department of Pathology and the Hektoen Institute for Medical Research of Cook County Hospital, Chicago, presented for publication by Daniel S. Kushner, M.D., and Paul B. Szanto, M.D.

Clinical Data and Discussion

Dr. Edmund F. Foley: A 48-year-old car washer entered Cook County Hospital with the chief complaint of abdominal pain. He had been well until five days prior to admission, when he noted persistent lower abdominal pain aggravated by walking. He was free of pain at rest. Two days later, he awoke with more severe generalized abdominal pain, radiating to the right side of the back, and associated with vomiting. He passed flatus but no stool. He was able to eat and defecate (with catharsis) on the two days before admission, but the pain persisted at the same level of intensity. Systemic review revealed a chronic, productive cough and postnasal drip of five months duration. There was no hemoptysis and no chest pain until the present illness when he began to have substernal and chest pain on the left when coughing. He had had night sweats and some loss of weight since onset of illness. His history included pneumonia in 1953, gonorrhea in 1933, and chronic conjunctivitis and lacrimation in 1941. He had had no previous gastrointestinal complaints.

Physical examination revealed a well-developed, well-nourished, cooperative man. His temperature was 100 F (37.8 C), pulse 90, respirations 28 per minute, and blood pressure 155/95 mm. Hg. There was a profuse conjunctival exudate. The abdomen was tender in all quadrants, especially on the left side. There was 2+ guarding and 1+ rebound tenderness but no distention. No viscera were enlarged, and no masses were palpated. Rectal examination was negative; a stool benzidine test was positive (3+).

It would seem that the patient had an acute abdomen of five days' duration. A diagnostic dilemma was created because, after five days, all the usual symptoms had been disguised by the secondary defense. A person with an acute abdomen, seen so late, generally has peritonitis, and the way in which he arrived at his peritonitis has become obscured. One should first consider acute appendicitis, then diverticulosis, diverticulitis, weeping diverticulum, perforated ulcer, and inflammation of other organs, such as an acute pancreatitis.

Gastric analysis revealed no free acid (no histamine given), and no reaction with benzidine dihydrochloride. Urinalysis showed acid reaction, albumin 4+, and no sugar or bile; microscopy revealed many red blood cells and somewhat fewer leukocytes and hyaline casts. These findings could result from an acute pancreatitis. A roentgenogram of the chest was negative. A roentgenogram of the abdomen revealed gas-distended intestines but no free air. This man was a car washer, raising the possibility of carbon tetrachloride intoxication. He had no pneumonitis or evidence of tuberculosis. There was no radiologic evidence of a closed-loop obstruction but simply a diffuse distention of the intestines with gas, which would be present in any type of ileus, especially from a five-day-old abdominal process.

The most disturbing findings were the initial nonprotein nitrogen level of 162 mg. per 100 ml. and serum amylase level of 256 units (Wolgemuth). (Amylase levels, when determined by a modification of the method of Wolgemuth, normally range to 32 units with blood and to 64 units with urine.) On the following day, the nonprotein nitrogen level was 230 mg. per 100 ml., serum creatinine level 17 mg. per 100 ml., and serum amylase level 8 units. On the fourth hospital day, the nonprotein nitrogen level was 216 mg. per 100 ml. and serum creatinine level 13 mg. per 100 ml. The serum amylase level was 8 units and the carbon dioxide combining power 34 cc. per 100 cc. On the sixth hospital day, the nonprotein nitrogen level was 252 mg. per 100 ml., creatinine level 22.5 mg. per 100 ml., serum sodium level 115 mEq. per liter, chloride level 74 mEq. per liter, potassium level 7.9 mEq. per liter, and carbon dioxide combining power 15 cc. per 100 cc. The hemoglobin level was 64%; erythrocyte count 3,510,000 per cubic millimeter, and leukocyte count 15,200 per cubic millimeter. A blood Kahn test was negative.

At this point we have a man who had a five-day-old surgical abdomen, with profound azotemia. If we look first at the azotemia as a diagnostic wedge, we would consider the traditional prerenal, renal, and postrenal mechanisms. Prerenal azotemia

---

Dr. Kushner is Associate Director of Medical Education, Cook County Hospital, and Instructor in Medicine, Northwestern University Medical School; Dr. Szanto is Director, Department of Pathology, Cook County Hospital, and Professor of Pathology, Chicago Medical School.

Dr. Foley is Head of the Department of Medicine, Cook County Hospital, and Professor of Medicine, University of Illinois College of Medicine.

is essentially the result of a certain dysfunction of the kidney. One must consider that the kidney does a tremendous amount of work. In the course of an hour, a barrel of blood runs through the kidneys, and in 24 hours, a barrel and a half of glomerular filtrate passes through, and from this filtrate, one quart of water is thrown out as urine. Blood flow to the kidney may be compromised by hemorrhage or by loss of water, as the result of dehydration, vomiting, diarrhea, chills, or diabetic coma. Blood may not get to the kidney because there is not enough propulsive power of the heart. Finally, the kidney may not get enough blood due to infection of the peritoneal cavity. Such prerenal azotemia is of itself reversible and it is spoken of as being prerenal when its duration or significance are not sufficiently important to register irreversible damage to the kidney itself. On the other hand, if renal ischemia leads to necrosis, the result is a so-called lower nephron nephrosis, acute nephrosis, or acute renal failure. The mechanism may be simple renal ischemia or a toxic agent which directly attacks the kidney per se, such as carbon tetrachloride or other heavy metals, certain toxins, and certain hypersensitivity states. These, then, are the prerenal situations in which the kidney may fail or its function may be disturbed, resulting in azotemia.

At the renal level, an end-stage-kidney may have been produced by glomerular nephritis, nephrosclerosis, chronic pyelonephritis, or even myeloma or amyloid or bilateral renal cortical necrosis. Postrenal azotemia may be due to obstructive uropathy, especially associated with infection. This occurs commonly in pyelonephritis with stones, though any condition leading to back pressure sufficient to produce hydronephrosis may produce a cystic type of kidney resembling polycystic disease. A relatively common situation is that of the woman with carcinoma of the cervix, invasion of both ureters, and azotemia secondary to hydronephrosis. In men, prostatism with infection may result in urosepsis, a malignant and vicious condition. Our patient went to the World's Fair, contracted gonorrhea, and probably was treated with protargol and sounds, leaving him with strictures; he entered in a state that would make us consider the possibility of an obstructive uropathy.

I think this was a patient with acute renal failure. The heart was not enlarged, there was no significant hypertension, and there was nothing to indicate preexisting renal disease. We are forced to consider that his azotemia was on the basis of acute renal failure, due either to prerenal causes or postrenal causes, perhaps related to hydronephrosis secondary to obstructive uropathy.

Therapy was commenced with constant gastric suction, intravenously given fluids, and electrolytes; 0.5 mg. of atropine and 600,000 units of procaine penicillin were given every 6 hr. On the next day, he was comfortable and free of pain but appeared ill. He coughed frequently—a deep husky, productive cough. He sat up readily when examined.

Physical examination revealed a blood pressure of 124/86 mm. Hg, maximum tenderness in the epigastrium, poorly-localized Murphy's test, and hypoactive intestinal sounds; otherwise the findings were as on admission. His teeth were blood-stained, and he was thought to be coughing up blood. The urethra was obstructed, and no catheter could be passed beyond the prostate.

On the second hospital day, pain returned and the patient continued to have abdominal pain and fever until he died, in spite of oxytetracycline being added to the therapy. A Foley catheter was introduced; the urine was initially clear but soon became bloody. Most of the tenderness was now in the right upper abdominal quadrant. A diagnostic abdominal paracentesis was negative. On the third day, the patient was restless and hallucinated. He was given 50 mg. of chlorpromazine four times a day. There was a uremic frost on the shoulders and upper arms. Total urinary output for the day was 100 cc. of bloody urine. This improved after that and rose to 2,000 cc. on the sixth day, but his condition continued to deteriorate, and he died on the seventh hospital day.

This man had acute renal failure associated initially with anuria, followed by a diuretic phase. The renal failure was predicated either on the basis of a postrenal condition, an obstructive uropathy with superimposed pyelonephritis producing total eventual failure, or a primary intra-abdominal condition leading to the findings of a surgical abdomen, producing a serum amylase level, five days after onset, of 256 units, with diffuse ileus and abdominal tenderness and ascites.

Pancreatitis notoriously produces acute renal failure, but against this is the high potassium level (ordinarily with pancreatitis, the potassium level is low). On the other hand, this is balanced by a renal shut-down, tending to elevate the potassium level. The serum amylase level was 256 units on admission and subsequently lower. This could mean that it had been even higher before admission. The one thing that speaks against the diagnosis of pancreatitis is the insidious and slow onset in contrast to the usual dramatic onset of acute hemorrhagic pancreatitis. We may, however, miss the diagnosis of pancreatitis, if we insist on a dramatic onset. Most patients with pancreatitis do not develop acute renal shut-down so rapidly. On the other hand, this can occur with any intra-abdominal condition.

Traditionally, there has been the feeling that disproportionate elevation of the creatinine over the nonprotein nitrogen level indicates an obstructive uropathy. I do not think this always holds. We have seen patients walking around with a creatinine level of 20 mg. per 100 ml. who have had glomerular nephritis. It would seem that this patient had an acute renal failure secondary to an acute abdominal catastrophe, probably in the nature of an acute pancreatitis and, secondary to that, perhaps a bilateral renal cortical necrosis.

Dr. Hildegard Schorsch: The roentgenograms were taken on the day of admission. The heart was essentially normal. A fine linear fibrotic density which was residual from an old infection was seen. The costophrenic angles were clear. A small nodular density in the left base appeared to be a nipple shadow. The diaphragm was at a normal level and no free air was seen in the chest film. The abdomen showed a moderate amount of gas scattered throughout. I do not think it was abnormally distended. A loop of the small intestine appeared to be distended, and there was a moderate amount of gas in the stomach. There were calcifications in the pelvic vessels. The right kidney could be readily seen and appeared normal. The left kidney could not be seen and was probably obstructed. There was the suggestion of a small amount of free air under the right leaf of the diaphragm.

Dr. Foley: If free air was seen, we would have to assume weeping of a hollow viscus.

Dr. Schorsch: I am not positive about the free air.

Dr. Foley: Was this picture taken before or after the paracentesis?

Dr. Schorsch: It was taken on the day of admission.

Dr. Robert Freeark: We saw the suspicious area that has been referred to but did not think it was conclusive. We chose to presume that the patient did not have free air in the abdominal cavity.

Dr. Donald Atlas: Since this was a case of acute renal failure, it falls into a category of potentially reversible renal disease. There should be more information as to the urinary output from day to day. Were the fluid intake and output measured? What fluids were given? Was there an electrocardiogram? Was consideration given to peritoneal or extraperitoneal dialysis? In patients with acute pancreatitis with renal failure, there is always an element of extreme shock.

Dr. Foley: Yes, and that speaks against this being pancreatitis. The patient was not in shock at any time. I think a certain number of patients with pancreatitis do develop acute renal failure without shock as the result of ischemia of the kidney secondary to infection, necrosis, and reflex irritation of the peritoneum, with contracture of the calyces of the kidney leading eventually to a backflow type of obstruction.

Dr. Atlas: Another entity that should be mentioned is hemorrhagic necrosis of the papillas which occurs in obstructive urosepsis. This man must have had urinary obstruction. The urine was also suggestive of this diagnosis, in that there were many red blood cells with little pus, which, with the rapid downhill course, is the classic picture.

Dr. Foley: I should have mentioned that. I considered an obstructive uropathy with sepsis and fulminating papillary necrosis.

Dr. Samuel J. Hoffman: What about the rebound tenderness in the left lower abdominal quadrant? If this was a true rebound tenderness, it means peritoneal irritation in that particular area. Could he have had a slow leak of some kind in, for instance, a diverticulum?

Dr. Foley: Yes, but in a five-day-old surgical abdomen, it is hard to tell how the irritation got there. By that time he had ileus and peritonitis, and the only way you could tell would be to trace back the history minute-by-minute.

Dr. Hoffman: The peritonitis could have been walled off.

Dr. Foley: Yes, but here was a man who had a relatively mild, acute surgical abdomen and developed this dramatic acute renal failure. This focuses our attention on some severe catastrophic condition like pancreatitis, but we are discouraged in that diagnosis because he did not present himself in shock. On the other hand, we know that patients with peritoneal infection may develop the same thing. I think this has to be construed as obstructive uropathy with infection, especially of the fulminating type. The fact that he had uremia could have elevated the serum amylase level, but if the amylase level had been elevated on the basis of uremia, I would not have anticipated that it would subside.

Dr. Frederick C. Steigmann: He had gross blood in the urine. Doesn't that point to obstructive uropathy as one of the main factors? Could not the acute abdomen have aggravated that?

Dr. Foley: I would agree that he had an obstructive uropathy with pyelonephritis and some necrosis of the renal papillas, and then a pancreatitis or an acute surgical abdomen could have been the terminal event.

Dr. Hoffman: Could an inflammatory mass that involves the ureter produce blood in the urine?

Dr. Foley: Yes, but he was catheterized, and that could produce bleeding.

Dr. John O'Donoghue: We had a patient in the past week with acute peritonitis of several days duration. At operation his abdomen contained pus, but a capable surgeon was not able to locate where that inflammatory reaction came from. In a patient with left-sided tenderness, guarding, and resistance, we cannot exclude appendicitis, because it can drain over the rectosigmoid junction to the gutter of the left side. There was also a suspicion here of free air, and we have to think of a ruptured viscus.

Dr. Freeark: How wise is it to investigate such a patient, other than the lower urinary tract, in the presence of a rapidly rising nonprotein nitrogen level? Would you advise cystoscopy and retrograde studies? Is there any hope that intravenous pyelogram (IVP) would offer any information?

Dr. Foley: The only thing the IVP would tell you would be to do a retrograde study.

Dr. Atlas: An IVP would not show much with the nonprotein nitrogen at this level. Some have recommended that if the cause is not apparent, cystoscopy with cautious probing of one ureter is indicated because sometimes a large calculus may be found which can be dislodged. Although this level of azotemia contraindicates IVP, it is not a contraindication for cautious cystoscopy.

Dr. Freeark: Is there any danger if one is sure of the uropathy?

Dr. Atlas: Yes, there is danger, but it is a calculated risk one must take in a patient who is otherwise certain to die.

Dr. Foley: I cannot be in total agreement with Dr. Atlas. This is an area in which one cannot generalize. One must evaluate the individual case. There are sufficient differences in each case so that the indications are clear or the contraindications are foremost. I do not think we should lay down a blanket rule to have cystoscopy in all uropathies.

Clinical Diagnosis.—The final clinical diagnosis was acute pancreatitis with acute renal failure, complicated by obstructive uropathy with bilateral renal cortical necrosis.

Pathological Data

Dr. Paul B. Szanto: The body was that of a well-developed, well-nourished man. The pleural cavities contained only a few cubic centimeters of serous fluid. The heart was enlarged (500 Gm.) and showed left ventricular hypertrophy. The coronary arteries were grossly normal. Microscopically, the myocardial fibers were thickened, the nuclei bulky, and old foci of myocardial fibrosis were scattered throughout. The smaller coronary arteries showed some thickening of their walls. The lungs were heavy (1,300 Gm.), and edematous. The peritoneal cavity was free of fluid. The gastrointestinal tract was normal.

The pancreas was enlarged (150 Gm.). Around and within the pancreas, there were numerous yellow opaque foci, measuring up to 0.5 cm. On the cut surface, especially in the head of the pancreas, numerous hemorrhagic foci were seen. The pancreatic duct measured 2 mm. in diameter. Microscopically, sections taken from the head of the pancreas revealed destruction of normal architectural pattern by fat necrosis, associated with leukocytic inflammatory reaction and extensive hemorrhages (fig. 1). In the body and tail of the pancreas, the acini were still preserved, though some were distorted due to edema and interlobular exudative inflammatory reaction. The islands of Langerhans were well-preserved. Throughout the pancreas, the interlobular connective tissue was increased, as evidence of a chronic pancreatic fibrosis, on which the recent acute pancreatitis was superimposed.

Before continuing the presentation of the pathological findings, let us inquire about the possible cause of pancreatitis in general.

Obstruction of Pancreatic Duct.—The common channel theory assumes reflux of bile into pancreatic duct due to obstruction of papilla of Vater caused by (1) calculus at papilla of Vater, (2) spasm of sphincter of Oddi, and (3) edema. A gallstone may be located in the pancreatic duct. Spasm of biliary and pancreatic ducts secondary to disease of the gallbladder may be present. Obstruction of the pancreatic duct without disease of the gallbladder may exist as (1) a stone (pancreatic calculus), (2) spasm of sphincter of papilla of Vater, (3) duodenitis with edema of papilla of Vater, (4) chronic inflammation or fibrosis of pancreas, (5) tumor of pancreas, (6) squamous metaplasia of the ducts, or (7) surgical ligature of the duct.

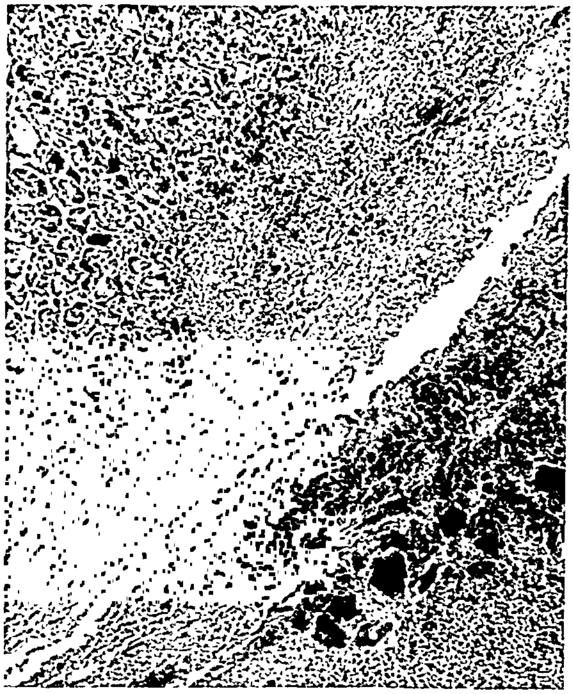

Fig. 1.—Extensive necrosis of pancreas with leukocytic inflammatory reaction.

Metabolic Disturbances.—Diabetes mellitus supposedly favors the development of pancreatitis due to the preexistent arteriosclerotic changes commonly associated with diabetes. In malnutrition the pancreas produces large amounts of protein, therefore, it requires large amounts of amino acids, especially methionine; deficiency in this amino acid, as produced experimentally by administration of ethionine,[1] leads to acute pancreatitis.

Alcohol.—An acute alcoholic bout may be the precipitating factor in pancreatitis due to (1) acute duodenitis, with swelling of the papilla of Vater, (2) increased secretin production leading to an increase in pancreatic juice, or (3) the combination of resistance to excretion due to edematous swelling of the duodenal mucosa and increased production of pancreatic juice, which will result in increased pressure within the pancreatic ducts, leading to rupture of the ducts and necrosis of the pancreatic parenchyma. Chronic alcoholism may lead to protein deficiency (including deficiency in methionine) which may explain the frequency of chronic relapsing pancreatitis in chronic alcoholism.

Trauma.—Accidental or surgical trauma (ligation of pancreatic duct) may result in pancreatitis.

Vascular Changes.—Experimentally, partial or complete obstruction of the pancreatic duct in rats has resulted in edema, inflammation, and atrophy, but no necrosis. When the ducts were occluded after the introduction of bile, no greater damage was observed than that which occurred after simple occlusion, but if temporary or permanent ischemia was produced simultaneously with obstruction to the ducts, necrosis resulted. Similarly, ligation of the pancreatic duct in dogs will lead to edema of the pancreas after administration of secretin. Additional ligation of the superior pancreaticoduodenal artery will result in massive necrosis of the pancreas. On the other hand, a careful review of 100 cases of malignant hypertension revealed not a single instance of diffuse hemorrhagic pancreatitis. Only focal microscopic lesions were seen in such cases.[2]

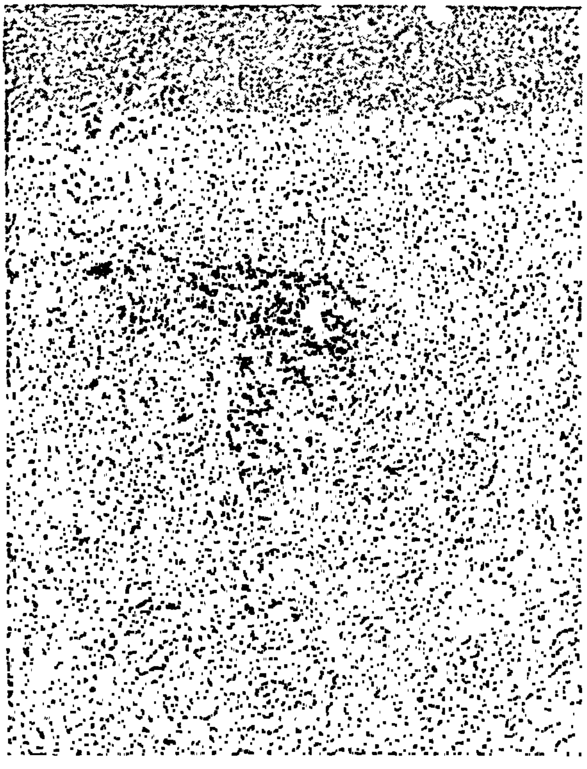

Fig. 2.—Fibrinoid necrosis of small artery with perivascular inflammatory reaction.

Infection.—Various types of infection,[3] e. g., generalized sepsis and virus diseases, such as mumps, may lead to pancreatitis. Direct extension of infection from the gallbladder to the pancreas has been assumed, but there is no direct connection between the lymphatic system of the gallbladder and that of the pancreas.

Allergy.—Injection of endotoxin of meningococci or Echerichia coli into the pancreatic duct, with subsequent intravenous injection of the same toxin, will lead to a massive necrosis.

In this patient, there was no common channel. The pancreatic duct and the common bile duct opened independently. Therefore, we cannot explain this pancreatitis on the basis of the common channel theory. The gallbladder and the bile ducts were normal. The liver was of normal size (1,400 Gm.). It was somewhat pale, and the normal lobular pattern was preserved. The kidneys were enlarged, each weighing 250 Gm. The surface was smooth but of flea-bitten appearance due to hemorrhagic foci, varying in size between 1 and 2 mm. in diameter. Microscopically, some of the glomeruli were hyalinized, but a few appeared smudgy, just as were the vasa efferentes. This smudginess of the arterioles and small arteries can be interpreted as evidence of arteriolar necrosis (necrotizing arteriolitis), superimposed on nephrosclerosis (fig. 2). In addition to these gross changes, the medulla showed numerous gray-white streaks, and, microscopically, extensive infiltration by polymorphonuclear leukocytes. Similarly, streaks of leukocytes were seen in the cortex with beginning formation of abscesses. This ascending pyelonephritis developed secondary to a purulent prostatitis, superimposed on a benign prostatic hypertrophy, which accounts for the clinical findings of urinary obstruction. In addition, to the ascending pyelonephritis, nephrosclerosis, and necrotizing arteriolitis, the distal convoluted tubules, Henle's loops, and excretory ducts contained heme casts, interpreted as evidence of hemoglobinuric nephrosis (lower nephron nephrosis) because of the simultaneous necrosis of these tubules and escape of heme casts from the disintegrating tubules. The necrotizing arteriolitis was not limted to the kidney; the perirenal and periadrenal fat tissue and the spleen presented the same vascular changes. In the pancreas, the arteriolar necrosis was present not only in areas of necrosis but also in those parts of the pancreas that were relatively well-preserved (fig. 3).

Comment

Twelve days before death, this patient developed severe abdominal pain and an elevated serum amylase level on the basis of acute hemorrhagic pancreatitis. He subsequently developed acute nephrosis (lower nephron nephrosis), which is a typical complication of hemorrhagic pancreatitis. Evidences of hypertension included the blood pressure of 155/95 mm. Hg, in the face of a shock-like state, cardiac enlargement with left ventricular hypertrophy, and nephrosclerosis. Finally, a purulent prostatitis led to lower urinary tract obstruction and ascending pyelonephritis.

In relation to the previously outlined multiple theoretical causes of pancreatitis, there are four possibilities to explain this combination of renal and pancreatic findings: First, the combination of hypertension and uremia led to generalized arteriolar necrosis, which in association with urosepsis, led to acute pancreatitis. Among the various theories about the etiology and pathogenesis of acute pancreatitis, the application of Shwartzman-Sanarelli phenomenon is worthy of consideration. Shwartzman induced severe hemorrhagic necrotic reactions in the skin of rabbits by intradermal injection of a cell-free filtrate of Salmonella typhosa, followed by intravenous injection of a small amount of this same filtrate 24 hours later. Applying this principle, it has been found that injection of a bacterial endotoxin in sublethal doses into a pancreatic duct of rabbits, followed by intravenous injection of the same antigen, resulted in fulminating pancreatitis.[4] Subsequent investigations revealed that antigenic specificity is not involved, e. g. the antigens used for sensitization and for provocation of the reaction need not be related.

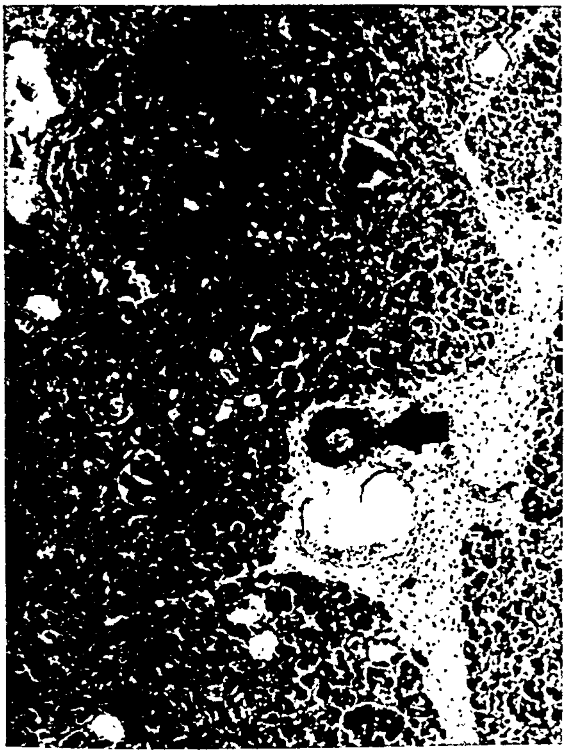

Fig. 3.—Fibrinoid necrosis of small artery in pancreas. Tissue in this area is relatively well preserved.

Later, Shwartzman showed that spontaneous sensitization of an organ may occur, in which case, a single intravenous injection of any antigen may suffice to cause a Shwartzman phenomenon.[5] On the basis of this observation, one could speculate that the necrotizing arteritis may have sensitized the pancreatic tissue and that a septicemia, secondary to the purulent prostatitis and acute pyelonephritis, may have provided the provocation leading to massive pancreatic necrosis. An alternative hypothesis could be that consequent to the pyelonephritis, circulating bacteria may have played the role of a sensitizing antigen, and the nonantigenic substances circulating in increased amounts in the blood in the uremic state may have acted as the provocative agents. It has been shown, after local (skin) sensitization, that such nonantigenic substances as agar or starch may be used for the provocative intravenous injection to produce the Shwartzman phenomenon.[6] If this explanation could be accepted, the necrotizing arteritis and arteriolitis would represent a kind of generalized Shwartzman phenomenon,[7] and the pancreatic necrosis would be a localized Shwartzman phenomenon.

The second possibility is that the patient had nephrosclerosis and then developed necrotizing arteriolitis which led to pancreatitis on a direct vascular basis, whereby the prostatic abscess and pyelonephritis would be only incidental. The third possibility is that the patient developed a pancreatitis in relation to an alcoholic bout and that the arteriolar necrosis was secondary to the liberated pancreatic trypsin. The fourth possibility is that the arteriolonephrosclerosis and necrotizing arteriolitis occurred coincidental with the acute hemorrhagic pancreatitis, with no cause or effect relationship. In our material, each of these entities alone occurs rather frequently, and one would expect a certain incidence of their coexistence.

Pathological Diagnosis.—The final pathological diagnosis was acute hemorrhagic pancreatitis, hemoglobinuric nephrosis, purulent prostatitis; ascending pyelonephritis, cardiac hypertrophy and dilatation, arteriolonephrosclerosis, and necrotizing arteriolitis.

RISK OF HEPATITIS REDUCED

ELSEWHERE in this issue (page 1735), in an article written with Drs. Wynn A. Sayman, Ross L. Gauld, and Shirley A. Star, Dr. J. Garrott Allen summarizes his long and careful study of the incidence of hepatitis in the recipients of blood and plasma at the University of Chicago. Both the plasma and whole blood used in this study were to a large extent obtained from the same donor population, and all plasma was pooled and stored for six months at an average temperature of 32 C. No other treatment of the plasma was carried out. Six-month follow-up studies on the occurrence of hepatitis were completed on sufficiently large groups of patients receiving whole blood, blood and plasma, and plasma only to yield conclusions which are considered to be statistically significant. A total of 305 individuals received pooled liquid plasma only. The total number of donors represented in the plasma given to these recipients was 12,345, and the average donor exposure per recipient was 41. Considering the large donor exposure represented by each infusion of pooled plasma, and the relatively high incidence of hepatitis in those receiving whole blood only (2.3%), the complete absence of hepatitis in those receiving plasma alone is truly impressive.

The National Academy of Sciences–National Research Council, with the support of the armed services and the Federal Civil Defense Administration, has held under continuous review since 1951 the accumulating evidence regarding the effectiveness of prolonged storage of plasma in the liquid state in the inactivation of the virus of serum hepatitis. Much of Dr. Allen's more recent work has been carried out under the auspices of the Army Research and Development Command, Office of the Surgeon General, and Dr. Ross Gauld has aided greatly in the statistical evaluation of the results. In addition to Dr. Allen's study, which was carried out on blood drawn into trisodium citrate, supporting data have been obtained on A. C. D. plasma stored for six months through the excellent follow-up studies carried out by Dr. Paul Hoxworth in Cincinnati and through a much larger, but somewhat less carefully controlled, series conducted by the Michigan State Health Department. The temperatures of storage have been slightly lower in these studies than that used by Dr. Allen, but well above average room temperature. No cases of hepatitis attributable to the plasma given were observed.

After the presentation of Dr. Allen's data at a meeting of the National Research Council's Subcommittee on Plasma in June, 1958, the subcommittee issued a statement to the effect that "the data now available [are] sufficiently convincing to warrant the conclusion that the storage of liquid plasma under these conditions [six months at approximately 32 C] can be used to produce a product of minimal infectivity." The members considered this method acceptable also for the salvage of plasma from outdated blood and that it was applicable to plasma drawn into either trisodium citrate or A. C. D. solution.

The most important additional evidence presented by Dr. Allen in this report points to the necessity for storage at temperatures higher than usual room temperature for effective inactivation of the hepatitis viruses. The experience described in which additional plasma, obtained from another blood bank where it had been stored for six months at an average temperature of 22 C, produced hepatitis in 17% of recipients, and the absence of hepatitis in recipients of plasma from that blood bank when the storage temperature was increased to 32 C, were very convincing. This experience helps to explain the apparent failure of so-called room temperature storage to inactivate the virus of serum hepatitis in the human volunteer studies so carefully carried out by Dr. Roderick Murray of the U. S. Public Health Service. In these studies, known infected plasma was stored for six months at 22 C and, although the incidence of hepatitis was greatly reduced after six months as compared with three months of storage, one case did occur in 19 individuals receiving the six-month-stored plasma. The level of 22 C was selected by Dr. Murray as his interpretation of average room temperature. In England, this might be interpreted as 18 C. The conditions described in Dr. Allen's present report therefore emphasize the danger of continuing to call this procedure for virus inactivation "room temperature storage."

Dr. Allen is now trying shorter periods of storage at higher temperatures than 32 C, which might permit a more convenient processing procedure. Future studies of this type may serve to define more clearly the relation of time to temperature in the inactivation of the hepatitis viruses. For the present, the NRC subcommittee considers it wisest to adhere to Dr. Allen's tested conditions of storage at approximately 32 C for six months.

One other major recommendation made by the NRC subcommittee is that, for general application of this method, the strictest possible care be given to proper bacteriological control and that, for safety in regard to bacterial contamination, either Seitz filtration or ultraviolet irradiation be added to the processing technique. Not all laboratories can expect to be as fortunate as Dr. Allen's in avoiding bacterial contamination, and even Dr. Allen has reported that 4% of all his plasma pools were found to be contaminated. The danger of bacterial growth in liquid plasma, not always producing effects visible to the eye, is well known, and led to use of the term "liquid dynamite" for such plasma during World War II when it was subjected to careful study by the Navy. However, with the addition of Seitz filtration and/or ultraviolet irradiation and with careful bacteriological control, this hazard can be reduced to a minimum. The problems involved in providing such control will in general make it more practical and economical for individual blood banks to send their plasma for treatment to central processing laboratories having the necessary specialized skills and equipment.

Six months of storage at approximately 32 C is one answer to the problem of providing a safe plasma preparation, but the NRC subcommittee calls attention to other possibilities now under careful evaluation. One method, the partial alcohol fractionation of plasma to remove fibrinogen and most of the globulin fractions, followed by heating for 10 hours at 60 C, has been licensed by the National Institutes of Health Division of Biologics Standards and offers a convenient and practical processing method for commercial application. Chemical sterilization also holds great promise, but this will require more extensive evaluation.

Meanwhile, Dr. Allen's procedure, when combined with adequate measures to achieve bacteriological sterility, remains the simplest and most practical available for the preparation of a safe plasma product and the salvage of plasma from outdated blood.

MISCONCEPTIONS ABOUT EYEGLASSES

At a Cornell Conference on Therapy[1] last fall ideas about many facets of ocular hygiene and the wearing of eyeglasses were aired. Dr. John McLean presented the conference with ammunition with which the general practitioner may combat false popular ideas. For example refractive errors have from time to time been held responsible for many symptoms including nausea, and the characteristic attacks of migraine. In all such cases another cause should be sought because uncorrected refractive errors can cause only lack of visual acuity, fatigue of the muscles of accommodation, and headache. This fatigue, like fatigue in any other muscle, disappears with rest and is not cumulative. Some patients with other symptoms are relieved when corrective glasses are worn, but in such cases the symptoms were psychosomatic and the relief is likely to be temporary. Dr. McLean said that relatively few headaches were of ocular origin, but many if not most ophthalmologists would disagree with this statement. A well-known consultant in this field believes that if a person attempts to do close work with glasses that do not cause obvious blurring but do not correct his refractive error a headache is very likely to develop. Failure to provide correction does not cause myopia to become progressively worse. This usually occurs throughout the growth period and the rate of progression is not influenced one way or another by the wearing of glasses. Presbyopia likewise progresses at its own rate regardless of corrective measures.

Many parents worry that eyestrain may be brought about by too much homework—a worry that schoolboys are often careful to foster. The same schoolboy may pore for hours on end over comic books or some other hobby involving near vision. The ocular fatigue of many a schoolboy can be more correctly attributed to boredom. From time to time patients with refractive errors come under the spell of a faddist who recommends that one throw away one's glasses and "strengthen" the eyes by means of exercises. The limited success of such faddists depends on their ability to teach persons to use their defective vision more effectively.

Children with severe uncorrected visual defects are severely handicapped. They tend to avoid playing with others and may be considered mentally retarded or queer. If glasses are prescribed for such children in time, not only their vision but also their social adjustment is improved. These and other points discussed made the conference one that we are fortunate to have preserved in type.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

A significant amount of work has been carried out by our Association—its committees of the House of Delegates and the Board of Trustees, the headquarters office, and individual staff members—in the last six months.

Too often, in my opinion, A. M. A. members are not aware of the accomplishments and current projects of their Association. For this reason I want to present briefly some of the highlights of the A. M. A.'s activities in the second half of 1958.

Two important reports will come before the House of Delegates for appropriate consideration and action next week in Minneapolis. One will be the study of the Commission on Medical Care Plans, covering three broad areas—the nature and method of various types of plans through which persons receive the services of physicians, the effect of these plans on quality and quantity of medical care, and the legal and ethical status of arrangements used by various plans. The second report will include the findings and recommendations of the Committee to Study A. M. A. Objectives and Basic Programs.

Two campaigns also have been launched this fall. One is the educational campaign on "the right of the patient to select his own physician." The other is the national drive against food faddism in cooperation with the Food and Drug Administration and the National Better Business Bureau.

I believe that our Association's more than 173,000 members can be extremely proud of our new fortnightly publication, *The AMA News*. With a press run of almost 250,000 *The News* now reaches more physicians than any other A. M. A. publication.

Other A. M. A. publications also have undergone expansion and change. THE JOURNAL, for example, has expanded its popular "Medicine at Work" section and has made it a regular feature. *Today's Health*, the Association's health magazine for the American family, has restyled its format and broadened its editorial approach with the result that circulation and advertising have increased. In addition, the 20th edition of the American Medical Directory was issued last month.

During the fall the Association held two special conferences, a planning session for medical society action in the field of aging and a symposium on adrenal steroids. The former was the kickoff to the profession's positive program for the aged.

Four other regular, but vital, conferences were conducted on foods and nutrition, mental health, civil defense, and public relations.

Special conferences also were held to discuss (1) the Association's proposed model law for labeling dangerous household and chemical products and (2) the Bill of Rights for the College Athlete, an A. M. A. effort to promote safer intercollegiate sports. In addition, the American Bar Association in August adopted the National Interprofessional Code (physicians and attorneys) approved last June by the House of Delegates.

Finally, and perhaps most significant of all, the Executive Vice-President, Dr. F. J. L. Blasingame, recently has reorganized the A. M. A. headquarters staff into six divisions (Council Administration, Scientific Publications, Business, Law, Communications, and Field Service) to promote efficiency, wider service to physicians and the public, and a smoother administrative operation.

Naturally, it is impossible to cover everything that's new in our Association in this brief mid-term report of my stewardship. But the items I have highlighted should prove conclusively that the A. M. A. is an enlightened, dynamic organization.

GUNNAR GUNDERSEN, M.D.
La Crosse, Wis.

MEDICAL NEWS

COLORADO

Woman Physician Honored.—Colorado will be represented for the first time in National Statuary Hall, Washington, D. C., and the statue will be that of the late Dr. Florence Rena Sabin. Congress paved the way for placement of the statue in the Capitol during the closing hours of the recent second session. Under a law that goes back to 1864, each state is allowed two statues of deceased, distinguished citizens. Dr. Sabin, who was noted for her research in the lymphatic system and tuberculosis, died in 1953. She will become the sixth physician honored in Statuary Hall. Others are Dr. Marcus Whitman, who died in 1857, Washington; Dr. John McCoughlin, 1857, Oregon; Dr. John Gorrie, 1855, Florida; Dr. Crawford W. Long, 1878, Georgia; and Dr. Ephriam McDowell, 1830, Kentucky.

ILLINOIS

New State Hospital Superintendents.—Dr. Thomas T. Tourlentes was made superintendent of the Galesburg State Research Hospital effective Sept. 1. Dr. Tourlentes previously was for four years assistant superintendent of the hospital. He is a diplomate of the American Board of Psychiatry and Neurology and clinical assistant professor of psychiatry at Northwestern University Medical School, Chicago. ——Dr. Verdamae Karr McKee became superintendent of the Dixon State School Aug. 1. Previously she was assistant superintendent of the East Moline State Hospital. Dr. McKee is the first woman in the history of the State of Illinois to head a major medical institution.——Dr. J. Herbert Maltz was appointed superintendent of the Chicago State Hospital effective July 16. Dr. Maltz, a native of New Jersey, is a diplomate of the American Board of Psychiatry and had served as assistant superintendent of the hospital previous to his appointment as superintendent.

Chicago

Hospital Grant.—A John A. Hartford Foundation, Inc., grant of $114,000 to the Passavant Memorial Hospital for metabolic studies in renal failure and edema and for research and clinical application of the artificial kidney has been announced. Mr. John N. Hatfield, director of the hospital, said that it will be used over a three-year period and to make possible the activation of the research, teaching, and patient care program which had been planned for the metabolic-artificial kidney unit in the new East Pavilion that will be in operation by late fall. The program will be under the direction of Dr. Arthur R. Colwell, Sr., chairman, department of medicine, Northwestern University Medical School. Dr. David P. Earle, professor of medicine, will coordinate the program as principal investigator with Dr. Francesco del Greco in immediate charge.

Surgeons Present Lecture Series.—The third series of lectures of the International College of Surgeons' Hall of Fame and School of the History of Surgery and Related Sciences held at the Hall of Fame, 1524 Lake Shore Drive, Chicago, began Oct. 21 when Ilza Veith, Ph.D., associate professor in the history of medicine, University of Chicago, the School of Medicine, presented "Changing Concepts of Disease." On Nov. 11, Dr. Morris Fishbein, professor emeritus of medicine, University of Chicago and University of Illinois College of Medicine, presented "Epochs in the History of Medicine." Subsequent lectures are planned as follows:

Dec. 2—The History of Hospitals, Dr. Charles U. Letourneau, director, program in hospital administration, Northwestern University Medical School.
Jan. 13—The History of Gynecology, Dr. Abraham F. Lash, clinical professor of obstetrics and gynecology, University of Illinois College of Medicine.
Feb. 3—The History of Neurosurgery, Dr. Percival Bailey, professor of neurology and neurological surgery, University of Illinois College of Medicine.
Feb. 24—Notes About the Role of Physicians in Our Military History, Dr. George F. Lull, Assistant to the President, American Medical Association.
March 24—Evolution of Medical Illustration, Thomas S. Jones, M.S., emeritus professor of medical and dental illustrations, University of Illinois College of Medicine.
April 14—The History of Surgery of Bones and Joints, Dr. Edward L. Compere, chairman, department of orthopaedic surgery, Northwestern University Medical School and Chicago Wesley Memorial Hospital.
May 5—Development of Otorhinolaryngology and Bronchoesophagology, Dr. Francis L. Lederer, head, department of otolaryngology, University of Illinois College of Medicine.
May 21—The History of Plastic Surgery, Dr. Wayne B. Slaughter, clinical professor in charge of plastic surgery, University of Wisconsin Medical School, Madison, and Stritch School of Medicine of Loyola University.

LOUISIANA

Dr. Ochsner Honored.—Dr. Alton Ochsner, professor of surgery, Tulane University School of Medicine, New Orleans, and director of surgery, Ochsner

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Clinic and Ochsner Foundation Hospital in New Orleans, has received the 1958 "Honor award" given by the Mississippi Valley Medical Society. The honor award is given from time to time to nonmembers of the society "who have made distinguished contributions to clinical medicine." The citation given in connection with the award reads in part: "Your contributions to the medical literature have not been confined to your several books, numerous chapters and more than 390 articles, for you have served as editor of several national medical periodicals and on the editorial board of a number of others. For these many impressive achievements you have been entrusted with the highest office in virtually every national surgical organization and some international ones."

MASSACHUSETTS

Dr. Coons Receives Research Award.—For the seventh Kimble Methodolgy Research Award sponsored by Kimble Glass Division, subsidiary of Owens-Illinois Glass Company, Toledo, Ohio, the award committee of Dr. Frank C. Lawler, chairman, Morris Scherago, D.V.M., and Henry Bauer, Ph.D., have chosen Dr. Albert H. Coons, Boston, to be the recipient. The work for which Dr. Coons was honored on Oct. 26 is "The Development of Fluorescent Antibody Techniques." From 1939 to the present Dr. Coons has held appointments at Harvard University, except from September, 1939-September, 1940, when he was assistant resident in medicine, Thorndike Memorial Laboratory, Boston City Hospital, and from April, 1942, to November, 1945, he was in the Medical Corps of the U. S. Army. At Harvard Medical School he has served as research fellow, instructor, associate, and assistant professor. Since 1953 he has been visiting professor of bacteriology and immunology at Harvard as well as a career investigator, American Heart Association.

MICHIGAN

Appoint Chairman of Department of Internal Medicine.—Appointment of Dr. William D. Robinson, a member of the University of Michigan Medical School faculty since 1944, as chairman of the department of internal medicine, effective Oct. 1, has been announced. He succeeds Dr. Cyrus C. Sturgis, who resigned as chairman in February, 1957, to devote full time to the practice of medicine. Dr. Paul S. Barker has served as acting chairman during the intervening period. Dr. Robinson served with the International Health Division of the Rockefeller Foundation for four years.

MINNESOTA

Judd-Plummer Lecture.—Dr. Thomas M. Durant, head, department of medicine, Temple University School of Medicine, Philadelphia, gave the annual Judd-Plummer Memorial Lecture Oct. 3 during the 34th annual meeting of the Alumni Association of the Mayo Foundation. Dr. Durant spoke on "Medical Education: Responsibilities and Potentialities." The Judd-Plummer Memorial Lecture was established in 1938 by the alumni association to honor the memory of Dr. Edward S. Judd, Mayo Clinic surgeon who died in 1935, and Dr. Henry S. Plummer, specialist in internal medicine of the Mayo Clinic, who died in 1936. The first lecture was given in 1941. Dr. Durant is a member of the editorial board of the *American Heart Journal*, and associate editor of the *American Journal of the Medical Sciences.*

NEW YORK

University Dedicates Nucleus of Medical Center.—The reconstructed Basic Sciences Building of the State University Upstate Medical Center in Syracuse was dedicated formally Oct. 21, with Gov. W. Averell Harriman the principal speaker. Three new wings and a fourth floor have been added. The new building has been reconstructed from a structure completed in 1937, when the medical college was a part of Syracuse University. Now it is a unit of State University of New York. Designed for four classes of 100 medical students each, the Basic Sciences Building contains complete medical science instructional facilities and ample quarters for faculty and student research projects. The six basic science departments located in the building are those of anatomy, microbiology, pathology, physiology, pharmacology, and biochemistry. The Basic Sciences Building is the nucleus of the Upstate Medical Center, which eventually will include colleges of nursing, dentistry, medical technology, and other health fields. The next step in the university's plan for the Medical Center is a new teaching hospital, for which plans are now being drawn. During the week of dedicatory events, members of the Onondaga County Medical Society toured the new building and held a meeting there Tuesday evening. On Oct. 22 the annual Hilda Freeman Silverman lecture was presented in the auditorium by Dr. Alexander D. Langmuir, chief of the U. S. Public Health Service Communicable Disease Center, Atlanta, Ga. The year ending in June, 1959, has been named Dedication Year at the Upstate Medical Center in honor of completion of the new Basic Sciences Building, and a number of special scientific programs and other events are being held.

New York City

Dr. Salisbury Honored.—On the retirement as medical director for many years of the United Fruit Company, Dr. Edward I. Salisbury was guest of honor at a luncheon in New York City, Oct. 17, presented by Dr. Charles M. Gratz, of Greenwich, Conn. The principal speaker at the luncheon was the Honorable Spruille Braden, former American

Ambassador to Cuba and Guatemala, and among the guests were Drs. Richardo Aguilar and Ruben Aguilar, father and son of Guatemala, whose family has been active through four generations in surgery in Central America.

Dr. Scheie to Give Schoenberg Lecture.—The annual Schoenberg Memorial Lecture sponsored jointly by the New York Society for Clinical Ophthalmology and the National Society for the Prevention of Blindness will be given at 8:15 p. m., Dec. 1, at the New York Academy of Medicine, 2 E. 103rd St. Dr. Harold G. Scheie, professor of ophthalmology, University of Pennsylvania School of Medicine, Philadelphia, will give an address on "Management of Infantile Glaucoma." Dr. Mark J. Schoenberg, a New York ophthalmologist, was prominent in the work of both the National Society for the Prevention of Blindness and the New York Society for Clinical Ophthalmology. Since his death in 1945, the two societies have joined each year in honoring his memory. All physicians will be welcome.

Personal.—Dr. Hector Mazzella has been appointed visiting professor of physiology at the State University of New York Downstate Medical Center in Brooklyn. Dr. Mazzella is a professor of physiology at the School of Medicine in Montevideo, Uruguay, and is the author of many articles in scientific subjects.——At a special ceremony Sept. 19 Dr. Ben-Henry Rose was decorated by the Haitian Government with the medallion and certificate of the appointment as an Officer in the National Order of Merit and Honor of the Republic of Haiti "for meritorious professional services rendered to Haitians upon his several visits to that country, and to their compatriots residing in New York."——Dr. James B. Amberson, III, professor of medicine emeritus at Columbia University's College of Physicians and Surgeons and former visiting physician in charge of Bellevue Hospital's chest service, has been named general director of the New York Tuberculosis and Health Association, where he previously held the title of director. At the same time Mr. Irving Mushlin, associate director since 1955, was named managing director of the association.

PENNSYLVANIA

Philadelphia

Stieglitz Memorial Lecture.—The first Edward Julius Stieglitz Memorial Lecture was given recently at a banquet in connection with Lankenau Hospital's two-day research conference on "Bone As A Tissue." Clive M. McCay, Ph.D., professor of nutrition at Cornell University Medical College, New York, since 1934, presented the memorial address on "Nutritional Influences on Bone." The lectureship was established to commemorate Dr. Stieglitz, who died last summer. A pioneer in geriatrics, Dr. Stieglitz authored the "Care of the Aging and the Aged" and "Medical Care of Later Maturity."

Shop for Surgical Needs.—At the Cardiovascular Institute, Hahnemann Medical College and Hospital, a plaque has been placed honoring the members of the Philadelphia Chapter, Machinery Dealers National Association, who donated machine tools and money to the Mary Bailey Foundation for a specialized shop. The metal-working machine shop, located in the Cardiovascular Institute, will be used by doctors and technicians to produce new, experimental surgical instruments, tools, and equipment needed in the advance study of heart surgery. The effort began two years ago when officials of the foundation asked the Philadelphia Chapter of MDNA for assistance in planning and equipping such a shop, which would eventually reduce the cost of such instruments and equipment.

TENNESSEE

Symposiums on Nutrition and Medical Education.—On Dec. 4 and 5 the Vanderbilt University School of Medicine, Nashville, will present two symposiums in honor of John Barlow Youmans on "Nutrition in Internal Medicine," with Dr. Frank B. Berry, assistant secretary of defense (health and medical), Washington, D. C., as chairman, and "Medical Education," with Dr. Joseph C. Hinsey, director, New York Hospital–Cornell Medical Center, New York City, as chairman. A subscription dinner is planned for 7 p. m., Dec. 4. A panel discussion, "Medical Education—Its Future," will be moderated by Dr. Robert C. Berson and will include the following participants: Dr. Lowell T. Coggeshall, dean, Division of the Biological Sciences including the School of Medicine, University of Chicago; Dr. Lester J. Evans, executive associate, The Commonwealth Fund, New York City; Dr. C. Sidney Burwell, Samuel A. Levine professor of medicine, Harvard University, Boston; and Dr. Ward Darley, executive director, Association of American Medical Colleges, Evanston, Ill. For information write the Symposia Secretary, School of Medicine, Vanderbilt University, Nashville 5, Tenn.

WISCONSIN

Cancer Seminar in Milwaukee.—The annual cancer seminar sponsored by the Wisconsin Society of Pathologists and Milwaukee Chapter of the American Cancer Society will be presented Dec. 6, 1 p.m., at Marquette University School of Medicine, Milwaukee. The seminar will be on "Tumors of the Chest," moderated by Dr. William A. D. Anderson, of Miami, Fla. There will be a morning session devoted to clinical pathology presented by the membership. A limited supply of slide sets are available at $10 service charge. Requests should be directed to: Dr. Robert S. Haukohl, 561 N. 15th St., Milwaukee 3, Wis.

GENERAL

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Bahamas Surgical Conference.—The first Bahamas Surgical Conference will be held at the British Colonial Hotel, Nassau, Dec. 29-Jan. 17. Among the speakers will be:

Drs. Lowell F. Bushnell, Los Angeles; Robert E. Cassidy, James H. Ferguson, Francis N. Cooke, John J. Farrell, Donald W. Smith, Miami; Max G. Carter, New Haven; John M. Chamberlain, Gerald H. Pratt, Charles E. Rogers, New York; Lawrence S. Fallis, James Barron, Jean P. Pratt, Detroit; Lewis K. Ferguson, Arthur Finkelstein, Henry J. Tumen, Robert P. Glover, Louis E. Silcox, Philadelphia; Randolph L. Clark Jr., Edgar C. White, William O. Russell, Houston; Raymond H. Rigdon, Galveston; Philipp R. Rezek, Miami; Bella R. Hearst, Dallas; William A. Hopkins, Atlanta; Maurice S. Mazel, Chicago;; Karl P. Klassen, Columbus, Ohio; George G. McHardy, New Orleans.

The Sunday Evening Lecture will be given by Mr. M. E. Lerch, eastern director of public relations, Household Finance Corporation. Six movie films will be available for showing. Participants in the conference and their parties enjoy special reduced hotel rates at the British Colonial Hotel in Nassau, provided that reservations are made by writing directly to "Bahamas Conference," P. O. Box 4037, Fort Lauderdale, Fla. Reservations should be made at once. If reservations are made by telephone, call JAckson 3-7303 at Fort Lauderdale, Fla. Indicate the type of accommodation required.

Midwest Allergists Meet in Detroit.—The Sheraton Cadillac Hotel, Detroit, will be headquarters for the Midwest Forum on Allergy, Dec. 6-7, sponsored by the Michigan Allergy Society and including the allergy societies of Buffalo, Chicago, Cleveland, Michigan, Ohio Valley, Pittsburgh, and West Virginia. Dr. Sara Dubo, Northville, Mich., will present "Psychiatry and Allergy" as guest lecturer the morning of Dec. 6. The following panel discussions and participants are planned:

Drug Allergy, Drs. Edward A. Carr Jr., Ann Arbor, Mich.; Max Samter, Chicago; and Theodore L. Squier, Milwaukee.
Insect Allergy, Drs. Frank Perlman, Portland, Ore.; Karl D. Figley, Toledo, Ohio; Iredell M. Hinnant, Cleveland; and Howard Osgood, Buffalo, N. Y.
Occupation and Allergy, Drs. Seward E. Miller, Ann Arbor, Mich.; William R. Buckley, Rochester, N. Y.; Rex H. Wilson, Akron, Ohio; and Harold H. Gay, Midland, Mich.

A symposium the afternoon of Dec. 6 on "Corticotropin and Corticosteroids" will be moderated by Dr. Carl E. Arbesman, Buffalo, N. Y. Following dinner that evening Warren H. Wagner Jr., Ph.D., Ann Arbor, Mich., will present "Ragweed Pollen: Its Production, Emanation, Dissipation and Destruction." For information write Dr. John M. Sheldon, University Hospitals, Ann Arbor, Mich., General Chairman.

Chest Physicians Meet in Minnesota.—The Interim Session of the American College of Chest Physicians will be held on Nov. 29-30 at the Mayo Clinic and Kahler Hotel, Rochester, Minn., and on Dec. 1 at the Radisson Hotel, Minneapolis. The morning session Nov. 29 will consider thoracic and cardiovascular surgery followed by a motion picture session including seven films. That afternoon a pulmonary section and cardiac section will be held, and the banquet, presided over by Dr. Donald R. McKay, Buffalo, New York, president of the college, will be held that evening. Four round-table luncheons will be presented Nov. 30:

Disorders of Esophageal Motility, moderated by Dr. Charles F. Code, Rochester, Minn.
Bronchography, Indications and Techniques, Dr. Sheldon E. Domm, Knoxville, Tenn.
Surgical Treatment of Acquired Valvular Heart Disease, Dr. Robert P. Glover, Philadelphia.
Early Detection of Emphysema, Dr. Peter A. Theodos, Philadelphia.

Nine fireside conferences will be presented the evening of Nov. 30. A panel discussion, "Inhalation Therapy," moderated by Dr. Edwin R. Levine, Chicago, is planned for the evening of Dec. 1. For information write the American College of Chest Physicians, 112 E. Chestnut St., Chicago 11.

Missing Person Wanted.—The Salt Lake County (Utah) Sheriff's Office is seeking information on the whereabouts of Richard Nunley, aged 26, who has a light complexion, blue eyes, blond straight hair, is 5 ft. 10 in. in height, and weighs 160 lbs. On Sept. 3, Nunley and his 3-year-old son, Raymond Scott Nunley, left their home for a grocery store two blocks away. When they failed to return a few days later, the Salt Lake County Sheriff's Office was notified and a missing person broadcast was made. Later the Sheriff's Office was notified that Richard Nunley was seen in Montpelier, Idaho. This was the last information received on these people until late afternoon on Oct. 7, when the decomposed body of Raymond Nunley was found in a field two blocks from the store.

Richard Nunley.

Nunley was last seen wearing charcoal slacks, and a light shirt with pink dots. He has worked at theatres as an operator and handy man and may seek this type of employment.

His fingerprint classification is as follows:

26	L	25	W	MOM	21
	L	4	W	IOI	

If anyone knows Richard Nunley's whereabouts, they are requested to contact the Salt Lake County Sheriff, George Beckstead, City and County Building, Salt Lake City, Utah, or their local law enforcement office.

LATIN AMERICA

Zoonoses Center in Argentina.—The Rockefeller Foundation has made available some $10,000 to further the fight against the zoonoses in the Americas. The Pan American Zoonoses Center, established in 1956 in Azul, Argentina, 185 miles south of Buenos Aires, is the only institution of its kind. At present its work is concentrated on rabies, brucellosis, and hydatidosis. Work in the virus encephalitides, anthrax, leptospirosis, bovine tuberculosis, psittacosis, trichinosis, and salmonellosis will be increased as the facilities permit. The center offers many services: training, consultation, field demonstrations, confirmatory diagnostic tests, and research, under the administration of the Pan American Sanitary Bureau.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Part II only, April 21-22; Parts I and II, June 16-17; Part I only, Sept. 9-10. Examinations must be received at least six weeks in advance of a specific examination date. Examining centers established after close of registration. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates, Inc.: Stations around the world, Feb. 17. Deadline for foreign applications is Nov. 17. The following examination will be held Sept. 22 with application deadline of June 22. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Written.* Montgomery, June 16-18. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery 4.
ALASKA:* On application in Anchorage and Juneau. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.
ARIZONA:* *Written Examination and Reciprocity.* Phoenix, Jan. 14-16. Sec., Dr. Thomas H. Bate, 2910 North 7th Ave., Phoenix.

California: *Oral Examination*, San Francisco, November 15. *Oral and Clinical Examination for Foreign Medical School Graduates*. San Francisco, June 15; Los Angeles, August 17; San Francisco, November 16. Sec., Dr. Louis E. Jones, 1020 N Street, Sacramento.

Colorado: *Written*. Denver, Dec. 9-10. Exec. Sec., Mrs. Beulah H. Hudgens, 715 Republic Bldg., Denver 2.

Connecticut:* *Homeopathic. Examination*. Derby, Jan. 13. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: *Written Examination and Endorsement*. Dover, Jan. 13-15, Jan. 22. Sec., Dr. Joseph S. McDaniel, Professional Bldg., Dover.

Florida:* *Examination*. Miami Beach, Nov. 23-25. Sec., Dr. Homer L. Pearson, 901 N. W. 17th St., Miami 36.

Georgia: *Examination and Reciprocity*. Atlanta, June. Sec., Mr. C. L. Clifton, 224 State Capitol, Atlanta 3.

Guam: *Subject to Call*. Act. Sec., Dr. F. L. Conklin, Agana.

Idaho: *Examination and Endorsement*. Boise, Jan. 12-14. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination and Reciprocity*. Chicago, Jan. 26-30. Supt. of Registration, Mr. Fredric B. Selcke, Capitol Bldg., Springfield.

Iowa:* *Examination and Endorsement*. Des Moines, Dec. 8-10. Exec. Sec., Mr. Ronald V. Saf, State Office Bldg., Des Moines 19.

Kentucky: *Examination*. Louisville, Dec. 8-10. Sec., Dr. Russell E. Teague, 620 South Third St., Louisville 2.

Louisiana: *Examination and Reciprocity*. New Orleans, Dec. 11-13. Sec., Dr. Edwin H. Lawson, 930 Hibernia Bank Bldg., New Orleans 12.

Maryland: *Examination*. Baltimore, Dec. 9-11. Sec., Dr. Frank K. Morris, 1211 Cathedral St., Baltimore 1.

Massachusetts: *Examination*. Boston, Jan. 13-16. Sec., Dr. Robert C. Cochrane, State House, Room 37, Boston 33.

Montana: *Examination and Reciprocity*. Helena, April 7. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

Nebraska:* *Examination*. Omaha, June. Director, Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

Nevada:* *Examination and Reciprocity*. Reno, Dec. 2. Sec., Dr. George H. Ross, 112 North Curry St., Carson City.

New Hampshire: *Examination and Endorsement*. Concord, Mar. 11-14. Sec., Dr. Edw. W. Colby, 61 So. State St., Concord.

New York: *Examination*. Albany, Buffalo, New York and Syracuse, Dec. 2-5. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

North Carolina: *Reciprocity*. Southern Pines, Jan. 17. *Examination*. June. Asst. Sec., Mrs. Louise J. McNeill, 716 Professional Bldg., Raleigh.

North Dakota: *Examination and Reciprocity*. Grand Forks, Jan. 7-10. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Examination*. Columbus, Dec. 16-18. *Endorsement*. Columbus, Dec. 16-18. Sec., Dr. H. M. Platter, Wyandotte Bldg., Columbus 15.

Oklahoma:* *Examination*. Oklahoma City, June 2-3. Exec. Sec., Mrs. E. L. Haidek, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Examination*. Portland, Jan. 6-7. *Reciprocity*. Portland, Jan. 8-10. Exec. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland 4.

Pennsylvania: *Endorsement*. Harrisburg, Dec. 11-12. *Examination*. Philadelphia, Jan. 7-10. Sec., Mrs. Margaret G. Steiner, Box 911, Harrisburg.

Rhode Island:* *Examination*. Providence, Jan. 8-9. Admin., Division of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Endorsement*. Columbia, Dec. 9. Sec., Dr. H. E. Jervey, Jr., Blanding Bldg., Columbia.

South Dakota:* *Examination*. Sioux Falls, Jan. 20-21. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:* *Examination*. Memphis, Dec. 17-18. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Texas:* *Examination and Reciprocity*. Fort Worth, Dec. 4-6. Sec., Dr. M. H. Crabb, 1714 Medical Arts Building, Fort Worth 2.

Utah: *Examination*. Salt Lake City, July 8-10. Dir., Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

Virginia: *Examination and Reciprocity*. Richmond, Dec. 4-6. Address: Virginia Board of Medical Examiners, 631 First St., S. W., Roanoke.

Washington:* *Examination*. Seattle, Jan. 12-14. Sec., Mr. Thomas A. Carter, Capitol Bldg., Olympia.

West Virginia: *Examination and Reciprocity*. Charleston, Jan. 5-7. Sec., Dr. Newman H. Dyer, State Office Bldg. No. 3, Charleston 5.

Wisconsin:* *Examination and Reciprocity*. Madison, Jan. 13-15. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., 1 West Wilson St., Madison.

Wyoming: *Examination and Reciprocity*. Cheyenne, Feb. 2. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: *Examination*. Tucson, Dec. 16. Sec., Mr. Herman E. Bateman, University of Arizona, Tucson.

Colorado: *Examination and Reciprocity*. Denver, Dec. 3-4. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

Connecticut: *Examination*. New Haven, Feb. 14. Exec. Asst., Mrs. Regina G. Brown, 258 Bradley St., New Haven 10.

Florida: *Examination*. Miami, June 6. Sec., Mr. M. W. Emmel, University of Florida, Box 340, Gainesville.

Iowa: *Examination*. Des Moines, Jan. 13. Sec., Dr. Elmer W. Hertel, Wartburg College, Waverly.

Kansas: *Endorsement*. Kansas City, Jan. 14. *Examination*. Kansas City, Jan. 16-17. Sec., State Board of Healing Arts, Dr. F. J. Nash, New Brotherhood Bldg., Kansas City.

Michigan: *Examination*. Ann Arbor and Detroit, Feb. 12-13. Sec., Mrs. Anne Baker, 116 Stevens T. Mason Bldg., West Michigan Ave., Lansing.

Minnesota: *Examination*. Minneapolis, Jan. 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.

Nevada: *Examination and Reciprocity*. Reno, Dec. 2. Sec., Dr. Donald G. Cooney, Box 9005, University of Nevada, Reno.

New Mexico: *Examination*. Santa Fe, Jan. 18. Sec., Mrs. Marguerite Cantrell, Box 1522, Santa Fe.

Oklahoma: *Examination*. Oklahoma City, Mar. 27-28. Exec. Sec., Mrs. L. Haidek, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination*. Portland, Dec. 6. Sec., Dr. Earl M. Pallett, Box 5175, Eugene.

Rhode Island: *Examination*. Providence, Nov. 19. Admin. of Professional Regulation, 366 State Office Bldg., Providence.

South Dakota: *Examination*. Vermillion, Dec. 5-6. Sec., Dr. Gregg M. Evans, 310 East 15th St., Yankton.

Tennessee: *Examination*. Memphis, Dec. 31-Jan. 1. Sec., Dr. O. W. Hyman, 62 South Dunlap St., Memphis 3.

Texas: *Examination*. April 1959. Certificates issued by reciprocity and waiver on the first and fifteenth of each month. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Washington: *Examination*. Seattle, Jan. 7-8. Sec., Mr. Thomas A. Carter, Capitol Bldg., Olympia.

Wisconsin: *Examination*. Milwaukee, Dec. 6, Madison, Apr. 4. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

---

*Basic Science Certificate required.

DEATHS

Allen, Samuel Shelhorn Ⓜ Macomb, Ill.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; on the staff of St. Francis Hospital; died in Memorial Hospital, Carthage, Sept. 19, aged 75.

Alston, Lucius Charles, Mesa, Ariz.; University of West Tennessee College of Medicine and Surgery, Memphis, Tenn., 1918; served overseas during World War I; died in Long Beach, Calif., Sept. 16, aged 66, of arteriosclerosis.

Bernard, Melamed Benjamin Ⓜ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1909; veteran of World War I; died in the Veterans Administration Hospital Sept. 30, aged 74, of intracranial hemorrhage.

Coffman, John Marvin Ⓜ Owensboro, Ky.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1912; died in the Owensboro –Daviess County Hospital Sept. 25, aged 80.

Conwell, John William, Cleveland; Western Reserve University School of Medicine, Cleveland, 1918; served on the faculty of his alma mater; past-governor of the Ohio State University Alumni Association in Ohio and past-president of the Cuyahoga County Alumni Association; during World War II in the Coast Guard Auxiliary and the Cleveland Heights Civil Defense Organization; associated with the Leonard C. Hanna Pavilion of the University Hospitals of Cleveland; died Sept. 23, aged 66.

Dreiss, Adolph Martin Ⓜ San Antonio, Texas; University of Texas School of Medicine, Galveston, 1919; died in the Santa Rosa Hospital July 24, aged 64, of cerebral hemorrhage.

Engelhardt, Carolina Sylvia Ruth, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1907; a charter member of the Woman's Medical College Hospital; died in Heidelberg, Germany, Aug. 24, aged 82.

Warren W. Furey, M.D., 1898-1958.

Furey, Warren William Ⓜ Chicago, a member of the Board of Trustees of the American Medical Association, died Nov. 19, aged 60, of coronary occlusion, while attending a meeting of the Radiological Society of North America. Dr. Furey was born in Chicago Jan. 8, 1898. He received his medical degree from Northwestern University Medical School in Chicago in 1923, and interned at the Mercy Hospital. Since April 1954, he had been a clinical professor of radiology at the Stritch School of Medicine of Loyola University, where he joined the faculty in 1927 as clinical assistant in orthopedic surgery; he was promoted to clinical instructor in orthopedic surgery in March 1929, transferred from orthopedic surgery to roentgenology, as a clinical assistant in October 1930; promoted to clinical associate in roentgenology in December 1931 and was promoted to to assistant clinical professor of roentgenology in December 1944. A specialist certified by the American Board of Radiology, Dr. Furey was a member of the American Roentgen Ray Society, International College of Surgeons, American Radium, and the American College of Radiology, of which he was president in 1955 and at one time treasurer. In 1950 he was president of the Radiological Society of North America and in 1954 was presented with its gold medal and citation for his long service to medicine and radiology. In 1955 he received the alumni medal of Loyola University and the following year an alumni citation from Northwestern University. In 1948 he was president of the Chicago Medical Society. Since 1956 Dr. Furey has been president of the Tuberculosis Institute of Chicago and Cook County. From 1950 to 1955 he was president of the Illinois Medical Service (Blue Shield) and from 1951 to 1955 secretary of the Blue Shield Commission. He was chief radiologist at the Little Company of Mary Hospital in Evergreen Park, Ill., and the Mercy Hospital, and radiological consultant at Lewis Memorial Maternity Hospital. Dr. Furey was general chairman of the local committee on arrangements for the American Medical Association meeting in Chicago in June 1948; from 1948 to 1957, he was a member of the House of Delegates of the American Medical Association. In 1955 he became a member of the Council on Constitution and Bylaws and only last June elected a member of the Board of Trustees.

Ⓜ Indicates Member of the American Medical Association.

Ganey, Joseph Matthew Sr., Ⓜ Waterford, Conn.; born Nov. 8, 1878; College of Physicians and Surgeons, Baltimore, 1904; for 16 years served on the board of education and was president at the time of his resignation in 1934; served overseas during World War I and his decorations included four campaign bars on a service ribbon and a Distinguished Service Cross; in 1933 appointed to the Public Health Council of the State Health Department; in 1940 named to the Selective Service Board for New London, Windham, Middlesex and Tolland counties; for many years was with the U. S. Public Health Service, serving as quarantine officer for the Port of New London; served as Waterford medical examiner for 15 years, resigning in 1953; for many years health officer and school physician; on the staff of the Lawrence and Memorial Associated Hospitals, New London; died in Preston Sept. 9, aged 79, of coronary heart disease.

Gerwig, Henry Eugene Ⓜ Downing, Mo.; Barnes Medical College, St. Louis, 1902; died Sept. 9, aged 83, of adenocarcinoma of the prostate.
